DISSERTATION SECOND:

EXHIBITING A GENERAL VIEW

OF THE

PROGRESS OF MATHEMATICAL AND PHYSICAL SCIENCE,

SINCE THE REVIVAL OF LETTERS IN EUROPE.

By JOHN PLAYFAIR,

PROFESSOR OF NATURAL PHILOSOPHY IN THE UNIVERSITY OF EDINBURGH,
FELLOW OF THE ROYAL SOCIETY OF LONDON,
AND SECRETARY OF THE ROYAL SOCIETY OF EDINBURGH.

DISSERTATION SECOND.

PART I.

In conformity to the plan which has been traced and executed with so much ability in the First Dissertation, I am now to present the reader with an historical sketch of the principal discoveries made in Natural Philosophy, from the revival of letters down to the present time. In entering on this task, and on looking at the instructive but formidable model already set before me, I should experience no small solicitude, did I not trust that the subject of which I am to speak, in order to be interesting, needs only to be treated with clearness and precision. These two requisites I will endeavour to keep steadily in view.

In the order which I am to follow, I shall be guided solely by a regard to the subserviency of one science to the progress of another, and to the consequent priority of the former in the order of regular study. For this reason, the history of the pure Mathematics will be first considered, as that science has been one of the two principal instruments applied by the moderns to the advancement of natural knowledge. The other instrument is Experience ; and, therefore, the principles of the inductive method, or of the branch of Logic which teaches the application of experiment and observation to the interpretation of nature, must be the second object of inquiry ; and in this article I shall give an account of Bacon's Philosophy, as applied to Physical investigation. After these two sections, which may in some measure be considered as introductory, I am to treat of Na-

tural Philosophy, under the divisions of Mechanics, Astronomy, and Optics. Under the general denomination of Mechanics I include the Theory of Motion, as applied not only to solids, but to fluids, both incompressible and elastic. Optics I have placed after Astronomy, because the discoveries in Mechanics have much less affected the progress of the former of these sciences than of the latter. To these will succeed a sixth division, containing the laws of the three unknown substances, if, indeed, they may be called substances,—Heat, Electricity, and Magnetism. These, though very different, agree in some general characters. They permeate all substances, though not with the same facility; and, if other bodies had been formed in the same manner with them, the idea of impenetrability would never have been suggested to the mind. They seem to receive motion, without taking any away from the body which communicates it; so that they can hardly be considered as inert. Two of them, Heat and Electricity, are perceived by the sense of touch; but the impression which they make does not convey an idea of resistance. The third is not perceived by touch; and, therefore, all the three might be denominated impalpable substances. If they have any gravity, it cannot be appreciated; and, for these reasons, had it not too paradoxical an appearance, we might class them together as *material*, but *incorporeal* substances. We know, indeed, nothing of them but as powers, transferable from one body to another; and it is in consequence of this last circumstance alone that they are entitled to the name of substances.

Though the general design of this historical sketch extends from the revival of letters to the beginning of the nineteenth century, I shall, in the present Part, confine myself entirely, as has been done in the first Discourse, to the period preceding the end of the seventeenth century, or, more precisely, to that preceding the invention of the fluxionary calculus, and the discovery of the principle of gravitation;—one of the most remarkable epochas, without doubt, in the history of human knowledge.

Section I.

MATHEMATICS.

1. Geometry.

The great inheritance of mathematical knowledge which the ancients bequeathed to posterity could not, on the revival of learning, be immediately taken possession of, nor could even its existence be discovered, but by degrees. Though the study of the Mathematics

had never been entirely abandoned, it had been reduced to matters of very simple and easy comprehension, such as were merely subservient to practice. There had been men who could compute the area of a triangle, draw a meridian line, or even construct a sun-dial, in the worst of times; but between such skill, and the capacity to understand or the taste to relish, the demonstrations of Euclid, Apollonius, or Archimedes, there was a great interval, and many difficulties were to be overcome, for which much time, and much subsidiary knowledge, were necessary. The repositories of the ancient treasures were to be opened, and made accessible; the knowledge of the languages was to be acquired; the manuscripts were to be decyphered; and the skill of the grammarian and the critic were to precede, in a certain degree, that of the geometrician or the astronomer. The obligations which we have to those who undertook this laborious and irksome task, and who rescued the ancient books from the prisons to which ignorance and barbarism had condemned them, and from the final destruction by which they must soon have been overtaken, are such as we can never sufficiently acknowledge; and, indeed, we shall never know even the names of many of the benefactors to whom our thanks are due. In the midst of the wars, the confusion, and bloodshed, which overwhelmed Europe during the middle ages, the religious houses and monasteries afforded to the remains of ancient learning an asylum, which a salutary prejudice forced even the most lawless to respect; and the authors who have given the best account of the revival of letters, agree that it is in a great measure to those establishments that we owe the safety of the books which have kept alive the scientific and literary attainments of Greece and Rome.

The study of the remains of antiquity gradually produced men of taste and intelligence, who were able to correct the faults of the manuscripts they copied, and to explain the difficulties of the authors they translated. Such were Purbach, Regiomontanus, Commandine, Maurolycus, and many others. By their means, the writings of Euclid, Archimedes, Apollonius, Ptolemy, and Pappus, became known and accessible to men of science. Arabia contributed its share towards this great renovation, and from the language of that country was derived the knowledge of many Greek books, of the originals of which, some were not found till long afterwards, and others have never yet been discovered.

In nothing, perhaps, is the inventive and elegant genius of the Greeks better exemplified than in their geometry. The elementary truths of that science were connected by Euclid into one great chain, beginning from the axioms, and extending to the properties of the five regular solids; the whole digested into such admirable order, and explained with such clearness and precision, that no similar work of superior excellence has appeared, even in the present advanced state of mathematical science.

Archimedes had assailed the more difficult problems of geometry, and by means of the method of Exhaustions, had demonstrated many curious and important theorems, with regard to the lengths and areas of curves, and the contents of solids. The same great geometer had given a beginning to physico-mathematical science, by investigating several propositions, and resolving several problems in Mechanics and Hydrostatics.

Apollonius had treated of the Conic Sections,—the Curves which, after the circle, are the most simple and important in geometry; and, by his elaborate and profound researches, had laid the foundation of discoveries which were to illustrate very distant ages.

Another great invention, the Geometrical Analysis, ascribed very generally to the Platonic school, but most successfully cultivated by the geometer just named, is one of the most ingenious and beautiful contrivances in the mathematics. It is a method of discovering truth by reasoning concerning things unknown, or propositions merely supposed, as if the one were given, or the other were really true. A quantity that is unknown, is only to be found from the relations which it bears to quantities that are known. By reasoning on these relations, we come at last to some one so simple, that the thing sought is thereby determined. By this analytical process, therefore, the thing required is discovered, and we are at the same time put in possession of an instrument by which new truths may be found out, and which, when skill in using it has been acquired by practice, may be applied to an unlimited extent.

A similar process enables us to discover the demonstrations of propositions, supposed to be true, or, if not true, to discover that they are false.

This method, to the consideration of which we shall again have an opportunity of returning, was perhaps the most valuable part of the ancient mathematics, inasmuch as a method of discovering truth is more valuable than the truths it has already discovered. Unfortunately, however, the fragments containing this precious remnant had suffered more from the injuries of time than almost any other.

In the fifteenth century, Regiomontanus, already mentioned, is the mathematician who holds the highest rank. To him we owe many translations and commentaries, together with several original and valuable works of his own. Trigonometry, which had never been known to the Greeks as a separate science, and which took that form in Arabia, advanced, in the hands of Regiomontanus, to a great degree of perfection, and approached very near to the condition which it has attained at the present day. He also introduced the use of decimal fractions into arithmetic, and thereby gave to that scale its full extent, and to numerical computation the utmost degree of simplicity and enlargement which it seems capable of attaining.

This eminent man was cut off in the prime of life; and his untimely death, says Mr Smith, amidst innumerable projects for the advancement of science, is even at this day a matter of regret.[1] He was buried in the Pantheon at Rome; and the honours paid to him at his death prove that science had now become a distinction which the great were disposed to recognise.

Werner, who lived in the end of this century, is the first among the moderns who appears to have been acquainted with the geometrical analysis. His writings are very rare, and I have never had an opportunity of examining them. What I here assert is on the authority of Montucla, whose judgment in this matter may be safely relied on, as he has shown, by many instances, that he was well acquainted with the nature of the analysis referred to. It is not a little remarkable that Werner should have understood this subject, when we find many eminent mathematicians, long after his time, entirely unacquainted with it, and continually expressing their astonishment how the ancient geometers found out those simple and elegant constructions and demonstrations, of which they have given so many examples. In the days of Werner, there was no ancient book known except the *Data* of Euclid, from which any information concerning the geometrical analysis could be collected; and it is highly to his credit, that, without any other help, he should have come to the knowledge of a method not a little recondite in its principles, and among the finest inventions either of ancient or of modern science. Werner resolved, by means of it, Archimedes's problem of cutting a sphere into two segments, having a given ratio to one another. He proposed also to translate, from the Arabic, the work of Apollonius, entitled *Sectio Rationis*, rightly judging it to be an elementary work in that analysis, and to come next after the *Data* of Euclid.[2]

Benedetto, an Italian mathematician, appears also to have been very early acquainted with the principles of the same ingenious method, as he published a book on the geometrical analysis at Turin in 1585.

Maurolycus of Messina flourished in the middle of the sixteenth century, and is justly regarded as the first geometer of that age. Beside furnishing many valuable translations and commentaries, he wrote a treatise on the conic sections, which is highly esteemed. He endeavoured also to restore the fifth book of the conics of Apollonius, in which that geometer treated of the *maxima* and *minima* of the conic sections. His writings all indicate

---

[1] *History of Astronomy*, p. 90. Regiomontanus was born in 1456, and died in 1496.

[2] See Montucla, Vol. I. p. 581.

a man of clear conceptions, and of a strong understanding; though he is taxed with having dealt in astrological prediction.

In the early part of the seventeenth century, Cavalleri was particularly distinguished, and made an advance in the higher geometry, which occupies the middle place between the discoveries of Archimedes and those of Newton.

For the purpose of determining the lengths and areas of curves, and the contents of solids contained within curve superficies, the ancients had invented a method, to which the name of Exhaustions has been given; and in nothing, perhaps, have they more displayed their powers of mathematical invention.

Whenever it is required to measure the space bounded by curve lines, the length of a curve, or the solid contained within a curve superficies, the investigation does not fall within the range of elementary geometry. Rectilineal figures are compared, on the principle of superposition, by help of the notion of equality which is derived from the coincidence of magnitudes both similar and equal. Two rectangles of equal bases and equal altitudes are held to be equal, because they can perfectly coincide. A rectangle and an oblique angled parallelogram, having equal bases and altitudes, are shown to be equal, because the same triangle, taken from the rectangle on one side, and added to it on the other, converts it into the parallelogram; and thus two magnitudes which are not similar, are shown to have equal areas. In like manner, if a triangle and a parallelogram have the same base and altitude, the triangle is shown to be half the parallelogram; because, if to the triangle there be added another, similar and equal to itself, but in the reverse position, the two together will compose a parallelogram, having the same base and altitude with the given triangle. The same is true of the comparison of all other rectilineal figures; and if the reasoning be carefully analyzed, it will always be found to be reducible to the primitive and original idea of equality, derived from things that coincide or occupy the same space; that is to say, the areas which are proved equal are always such as, by the addition or subtraction of equal and similar parts, may be rendered capable of coinciding with one another.

This principle, which is quite general with respect to rectilineal figures, must fail, when we would compare curvilineal and rectilineal spaces with one another, and make the latter serve as measures of the former, because no addition or subtraction of rectilineal figures can ever produce a figure which is curvilineal. It is possible, indeed, to combine curvilineal figures, so as to produce one that is rectilineal; but this principle is of very limited extent; it led to the quadrature of the *lunulæ* of Hippocrates, but has hardly furnished any other result which can be considered as valuable in science.

In the difficulty to which geometers were thus reduced, it might occur, that, by inscribing a rectilineal figure within a curve, and circumscribing another round it, two limits could be obtained, one greater and the other less than the area required. It was also evident, that, by increasing the number, and diminishing the sides of those figures, the two limits might be brought continually nearer to one another, and of course nearer to the curvilinear area, which was always intermediate between them. In prosecuting this sort of approximation, a result was at length found out, which must have occasioned no less surprise than delight to the mathematician who first encountered it. The result I mean is, that, when the series of inscribed figures was continually increased, by multiplying the number of the sides, and diminishing their size, there was an assignable *rectilineal* area, to which they continually approached, so as to come nearer it than any difference that could be supposed. The same limit would also be observed to belong to the circumscribed figures, and therefore it could be no other than the curvilineal area required.

It appears to have been to Archimedes that a truth of this sort first occurred, when he found that two-thirds of the rectangle, under the ordinate and abscissa of a parabola, was a limit always greater than the inscribed rectilineal figure, and less than the circumscribed. In some other curves, a similar conclusion was found, and Archimedes contrived to show that it was impossible to suppose that the area of the curve could differ from the said limit, without admitting that the circumscribed figure might become less, or the inscribed figure greater than the curve itself. The method of Exhaustions was the name given to the indirect demonstrations thus formed. Though few things more ingenious than this method have been devised, and though nothing could be more conclusive than the demonstrations resulting from it, yet it laboured under two very considerable defects. In the first place, the process by which the demonstration was obtained was long and difficult; and, in the second place, it was indirect, giving no insight into the principle on which the investigation was founded. Of consequence, it did not enable one to find out similar demonstrations, nor increase one's power of making more discoveries of the same kind. It was a demonstration purely synthetical, and required, as all indirect reasoning must do, that the conclusion should be known before the reasoning is begun. A more compendious, and a more analytical method, was therefore much to be wished for, and was an improvement, which, at a moment when the field of mathematical science was enlarging so fast, seemed particularly to be required.

Cavalleri, born at Milan in the year 1598, is the person by whom this great improvement was made. The principle on which he proceeded was, that areas may be considered as made up of an infinite number of parallel lines; solids of an infinite number of parallel

planes; and even lines themselves, whether curve or straight, of an infinite number of points. The cubature of a solid being thus reduced to the summation of a series of planes, and the quadrature of a curve to the summation of a series of ordinates, each of the investigations was reduced to something more simple. It added to this simplicity not a little, that the sums of series are often more easily found, when the number of terms is infinitely great, than when it is finite, and actually assigned.

It appears that a tract on stereometry, written by Kepler, whose name will hereafter be often mentioned, first led Cavalleri to take this view of geometrical magnitudes. In that tract, which was published in 1615, the measurement of many solids was proposed, which had not before fallen under the consideration of mathematicians. Such, for example, was that of the solids generated by the revolution of a curve, not about its axis, but about any line whatsoever. Solids of that kind, on account of their affinity with the figure of casks, and vessels actually employed for containing liquids, appeared to Kepler to offer both curious and useful subjects of investigation. There were no less than eighty-four such solids, which he proposed for the consideration of mathematicians. He was, however, himself unequal to the task of resolving any but a small number of the simplest of these problems. In these solutions, he was bold enough to introduce into geometry, for the first time, the idea of infinitely great and infinitely small quantities, and by this apparent departure from the rigour of the science, he rendered it in fact a most essential service. Kepler conceived a circle to be composed of an infinite number of triangles, having their common vertex in the centre of the circle, and their infinitely small bases in the circumference. It is to be remarked, that Galileo had also introduced the notion of infinitely small quantities, in his first dialogue, *De Mechanica*, where he treats of a cylinder cut out of a hemisphere; and he has done the same in treating of the acceleration of falling bodies. Cavalleri was the friend and disciple of Galileo, but much more profound in the mathematics. In his hands the idea took a more regular and systematic form, and was explained in his work on indivisibles, published in 1635.

The rule for summing an infinite series of terms in arithmetical progression had been long known, and the application of it to find the area of a triangle, according to the method of indivisibles, was a matter of no difficulty. The next step was, supposing a series of lines in arithmetical progression, and squares to be described on each of them, to find what ratio the sum of all these squares bears to the greatest square, taken as often as there are terms in the progression. Cavalleri showed, that when the number of terms is infinitely great, the first of these sums is just one-third of the second. This evidently led to the cubature of many solids.

Proceeding one step farther, he sought for the sum of the cubes of the same lines, and found it to be one-fourth of the greatest, taken as often as there are terms ; and, continuing this investigation, he was able to assign the sum of the nth powers of a series in arithmetical progression, supposing always the difference of the terms to be infinitely small, and their number to be infinitely great. The number of curious results obtained from these investigations may be easily conceived. It gave, over geometrical problems of the higher class, the same power which the integral calculus, or the inverse method of fluxions does, in the case when the exponent of the variable quantity is an integer. The method of indivisibles, however, was not without difficulties, and could not but be liable to objection, with those accustomed to the rigorous exactness of the ancient geometry. In strictness, lines, however multiplied, can never make an area, or any thing but a line ; nor can areas, however they may be added together, compose a solid, or any thing but an area. This is certainly true, and yet the conclusions of Cavalleri, deduced on a contrary supposition, are true also. This happened, because, though the suppositions that a certain series of lines, infinite in number, and contiguous to one another, may compose a certain area, and that another series may compose another area, are neither of them true ; yet is it strictly true, that the one of these areas must have to the other the same ratio which the sum of the one series of lines has to the sum of the other series. Thus, it is the ratios of the areas, and not the areas absolutely considered, which are determined by the reasonings of Cavalleri ; and that this determination of their ratios is quite accurate, can very readily be demonstrated by the method of exhaustions.

The method of indivisibles, from the great facility with which it could be managed, furnished a most ready method of ascertaining the ratios of areas and solids to one another, and, therefore, scarcely seems to deserve the epithet which Newton himself bestows upon it, of involving in its conceptions something harsh, (*durum*,) and not easy to be admitted. It was the doctrine of infinitely small quantities carried to the extreme, and gave at once the result of an infinite series of successive approximations. Nothing, perhaps, more ingenious, and certainly nothing more happy, ever was contrived, than to arrive at the conclusion of all these approximations, without going through the approximations themselves. This is the purpose served by introducing into mathematics the consideration of quantities infinitely small in size, and infinitely great in number ; ideas which, however inaccurate they may seem, yet, when carefully and analogically reasoned upon, have never led into error.

Geometry owes to Cavalleri, not only the general method just described, but many particular theorems, which that method was the instrument of discovering. Among these is

the very remarkable proposition, *that as four right angles, to the excess of the three angles of any spherical triangle, above two right angles, so is the superficies of the hemisphere to the area of the triangle.* At that time, however, science was advancing so fast, and the human mind was everywhere expanding itself with so much energy, that the same discovery was likely to be made by more individuals than one at the same time. It was not known in Italy in 1632, when this determination of the area of a spherical triangle was given by Cavalleri, that it had been published three years before by Albert Girard, a mathematician of the Low Countries, of whose inventive powers we shall soon have more occasion to speak.

The Cycloid afforded a number of problems, well calculated to exercise the proficients in the geometry of indivisibles, or of infinites. It is the curve described by a point in the circumference of a circle, while the circle itself rolls in a straight line along a plane. It is not quite certain when this curve, so remarkable for its curious properties, and for the place which it occupies in the history of geometry, first drew the attention of mathematicians. In the year 1639, Galileo informed his friend Torricelli, that, forty years before that time, he had thought of this curve, on account of its shape, and the graceful form it would give to arches in architecture. The same philosopher had endeavoured to find the area of the cycloid; but though he was one of those who first introduced the consideration of infinites into geometry, he was not expert enough in the use of that doctrine, to be able to resolve this problem. It is still more extraordinary, that the same problem proved too difficult for Cavalleri, though he certainly was in complete possession of the principles by which it was to be resolved. It is, however, not easy to determine whether it be to Torricelli, the scholar of Cavalleri, and his successor in genius and talents, or to Roberval, a French mathematician of the same period, and a man also of great originality and invention, that science is indebted for the first quadrature of the cycloid, or the proof that its area is three times that of its generating circle. Both these mathematicians laid claim to it. The French and Italians each took the part of their own countryman; and in their zeal have so perplexed the question, that it is hard to say on which side the truth is to be found. Torricelli, however, was a man of a mild, amiable, and candid disposition; Roberval of a temper irritable, violent, and envious; so that, in as far as the testimony of the individuals themselves is concerned, there is no doubt which ought to preponderate. They had both the skill and talent which fitted them for this, or even for more difficult researches.

The other properties of this curve, those that respect its tangents, its length, its curvature, &c. exercised the ingenuity, not only of the geometers just mentioned, but of Wren,

Wallis, Huygens, and, even after the invention of the integral calculus, of Newton, Leibnitz, and Bernoulli.

Roberval also improved the method of quadratures invented by Cavalleri, and extended his solutions to the case, when the powers of the terms in the arithmetical progression of which the sum was to be found were fractional; and Wallis added the case when they were negative. Fermat, who, in his inventive resources, as well as in the correctness of his mathematical taste,[1] yielded to none of his contemporaries, applied the consideration of infinitely small quantities to determine the *maxima* and *minima* of the ordinates of curves, as also their tangents. Barrow, somewhat later, did the same in England. Afterwards the geometry of infinites fell into the hands of Leibnitz and Newton, and acquired that new character which marks so distinguished an era in the mathematical sciences.

2. Algebra.

It was not from Greece alone that the light proceeded which dispelled the darkness of the middle ages; for, with the first dawn of that light, a mathematical science, of a name and character unknown to the geometers of antiquity, was received in Europe from Arabia. As early as the beginning of the thirteenth century, Leonardo, a merchant of Pisa, having made frequent visits to the East, in the course of commercial adventure, returned to Italy enriched by the traffic, and instructed by the science of those countries. He brought with him the knowledge of *Algebra;* and a late writer quotes a manuscript of his, bearing the date of 1202, and another that of 1228.[2] The importation of Algebra into Europe is thus carried back nearly 200 years farther than has generally been supposed, for Leonardo has been represented as flourishing in the end of the fourteenth century, instead of the very beginning of the thirteenth. It appears by an extract from his manuscript, published by the above author, that his knowledge of Algebra extended as far as quadratic equations. The language was very imperfect, corresponding to the infancy of the science; the quantities and the operations being expressed in words, with the help only of a few abbreviations. The rule for resolving quadratics by completing the square, is demonstrated geometrically.

Though Algebra was brought into Europe from Arabia, it is by no means certain that

---

[1] He also was very skilful in the geometric analysis, and seems to have more thoroughly imbibed the spirit of that ingenious invention than any of the moderns before Halley.

[2] M. Cossali of Pisa, in a Tract on the Origin of Algebra, 1797.

this last is its native country. There is, indeed, reason to think that its invention must be sought for much farther to the East, and probably not nearer than Indostan. We are assured by the Arabian writers, that Mahomet Ben Musa of Chorasan, distinguished for his mathematical knowledge, travelled, about the year 959, into India, for the purpose of receiving farther instruction in the science which he cultivated. It is likewise certain, that some books, which have lately been brought from India into this country, treat of algebra in a manner that has every appearance of originality, or at least of being derived from no source with which we are at all acquainted.

Before the time of Leonardo of Pisa, an important acquisition, also from the East, had greatly improved the science of arithmetic. This was the use of the Arabic notation, and the contrivance of making the same character change its signification, according to a fixed rule, when it changed its position, being increased tenfold for every place that it advanced towards the left. The knowledge of this simple but refined artifice was learned from the Moors by Gerbert, a monk of the Low Countries, in the tenth century, and by him made known in Europe. Gerbert was afterwards Pope, by the name of Silvester the Second; but from that high dignity derived much less glory than from having instructed his countrymen in the decimal notation.

The writings of Leonardo, above mentioned, have remained in manuscript; and the first printed book in Algebra is that of Lucas de Burgo, a Franciscan, who, towards the end of the fifteenth century, travelled, like Leonardo, into the East, and was there instructed in the principles of algebra. The characters employed in his work, as in those of Leonardo, are mere abbreviations of words. The letters *p* and *m* denote *plus* and *minus*; and the rule is laid down, that, in multiplication, *plus* into *minus* gives *minus*, but *minus* into *minus* gives *plus*. Thus the first appearance of Algebra is merely that of a system of short-hand writing, or an abbreviation of common language, applied to the solution of arithmetical problems. It was a contrivance merely to save trouble; and yet to this contrivance we are indebted for the most philosophical and refined art which men have yet employed for the expression of their thoughts. This scientific language, therefore, like those in common use, has grown up slowly, from a very weak and imperfect state, till it has reached the condition in which it is now found.

Though in all this the moderns received none of their information from the Greeks, yet a work in the Greek language, treating of arithmetical questions, in a manner that may be accounted algebraic, was discovered in the course of the next century, and given to the world, in a Latin translation, by Xylander, in 1575. This is the work of Diophantus of Alexandria, who had composed thirteen books of Arithmetical Questions, and is sup-

posed to have flourished about 150 years after the Christian era. The questions he resolves are often of considerable difficulty; and a great deal of address is displayed in stating them, so as to bring out equations of such a form, as to involve only one power of the unknown quantity. The expression is that of common language, abbreviated and assisted by a few symbols. The investigations do not extend beyond quadratic equations; they are, however, extremely ingenious, and prove the author to have been a man of talent, though the instrument he worked with was weak and imperfect.

The name of Cardan is famous in the history of Algebra. He was born at Milan in 1501, and was a man in whose character good and ill, strength and weakness, were mixed up in singular profusion. With great talents and industry, he was capricious, insincere, and vain-glorious to excess. Though a man of real science, he professed divination, and was such a believer in the influence of the stars, that he died to accomplish an astrological prediction. He remains, accordingly, a melancholy proof, that there is no folly or weakness too great to be united to high intellectual attainments.

Before his time very little advance had been made in the solution of any equations higher than the second degree; except that, as we are told, about the year 1508, Scipio Ferrei, professor of mathematics at Bologna, had found out a rule for resolving one of the cases of cubic equations, which, however, he concealed, or communicated only to a few of his scholars. One of these, Florido, on the strength of the secret he possessed, agreeably to a practice then common among mathematicians, challenged Tartalea of Brescia, to contend with him in the solution of algebraic problems. Florido had at first the advantage; but Tartalea, being a man of ingenuity, soon discovered his rule, and also another much more general, in consequence of which, he came off at last victorious. By the report of this victory, the curiosity of Cardan was strongly excited; for, though he was himself much versed in the mathematics, he had not been able to discover a method of resolving equations higher than the second degree. By the most earnest and importunate solicitation, he wrung from Tartalea the secret of his rules, but not till he had bound himself, by promises and oaths, never to divulge them. Tartalea did not communicate the demonstrations, which, however, Cardan soon found out, and extended, in a very ingenious and systematic manner, to all cubic equations whatsoever. Thus possessed of an important discovery, which was at least in a great part his own, he soon forgot his promises to Tartalea, and published the whole in 1545, not concealing, however, what he owed to the latter. Though a proceeding, so directly contrary to an express stipulation, cannot be defended, one does not much regret the disappointment of any man who would make a mystery of knowledge, or keep his discoveries a secret, for purposes merely selfish.

Thus was first published the rule which still bears the name of Cardan, and which, at this day, marks a point in the progress of algebraic investigation, which all the efforts of succeeding analysts have hardly been able to go beyond. As to the general doctrine of equations, it appears that Cardan was acquainted both with the negative and positive roots, the former of which he called by the name of false roots. He also knew that the number of positive, or, as he called them, true roots, is equal to the number of the changes of the signs of the terms; and that the coefficient of the second term is the difference between the sum of the true and the false roots. He also had perceived the difficulty of that case of cubic equations, which cannot be reduced to his own rule. He was not able to overcome the difficulty, but showed how, in all cases, an approximation to the roots might be obtained.

There is the more merit in these discoveries, that the language of Algebra still remained very imperfect, and consisted merely of abbreviations of words. Mathematicians were then in the practice of putting their rules into verse. Cardan has given his a poetical dress, in which, as may be supposed, they are very awkward and obscure; for whatever assistance in this way is given to the memory, must be entirely at the expence of the understanding. It is, at the same time, a proof that the language of Algebra was very imperfect. Nobody now thinks of translating an algebraic formula into verse; because, if one has acquired any familiarity with the language of the science, the formula will be more easily remembered than any thing that can be substituted in its room.

Italy was not the only country into which the algebraic analysis had by this time found its way; in Germany it had also made considerable progress, and Stiphelius, in a book of Algebra, published at Nuremberg in 1544, employed the same numeral exponents of powers, both positive and negative, which we now use, as far as integer numbers are concerned; but he did not carry the solution of equations farther than the second degree. He introduced the same characters for *plus* and *minus* which are at present employed.

Robert Recorde, an English mathematician, published about this time, or a few years later, the first English treatise on Algebra, and he there introduced the same sign of equality which is now in use.

The properties of algebraic equations were discovered, however, very slowly. Pelitarius, a French mathematician, in a treatise which bears the date of 1558, is the first who observed that the root of an equation is a divisor of the last term; and he remarked also this curious property of numbers, that the sum of the cubes of the natural numbers is the square of the sum of the numbers themselves.

The knowledge of the solution of cubic equations was still confined to Italy. Bombelli,

a mathematician of that country, gave a regular treatise on Algebra, and considered, with very particular attention, the irreducible case of Cardan's rule. He was the first who made the remark, that the problems belonging to that case can always be resolved by the trisection of an arch.[1]

Vieta was a very learned man, and an excellent mathematician, remarkable both for industry and invention. He was the first who employed letters to denote the known as well as the unknown quantities, so that it was with him that the language of algebra first became capable of expressing general truths, and attained to that extension which has since rendered it such a powerful instrument of investigation. He has also given new demonstrations of the rule for resolving cubic, and even biquadratic equations. He also discovered the relation between the roots of an equation of any degree, and the coefficients of its terms, though only in the case where none of the terms are wanting, and where all the roots are real or positive. It is, indeed, extremely curious to remark, how gradually the truths of this sort came in sight. This proposition belonged to a general truth, the greater part of which remained yet to be discovered. Vieta's treatises were originally published about the year 1600, and were afterwards collected into one volume by Schooten, in 1646.

In speaking of this illustrious man, Vieta, we must not omit his improvements in trigonometry, and still less his treatise on angular sections, which was a most important application of Algebra to investigate the theorems, and resolve the problems of geometry. He also restored some of the books of Apollonius, in a manner highly creditable to his own ingenuity, but not perfectly in the taste of the Greek geometry; because, though the constructions are elegant, the demonstrations are all synthetical.

About the same period, Algebra became greatly indebted to Albert Girard, a Flemish mathematician, whose principal work, *Invention Nouvelle en Algebre*, was printed

---

[1] A passage in Bombelli's book, relative to the Algebra of India, has become more interesting, from the information concerning the science of that country, which has reached Europe within the last twenty years. He tells us, that he had seen in the Vatican library, a manuscript of a certain Diophantus, a Greek author, which he admired so much, that he had formed the design of translating it. He adds, that in this manuscript he had found the Indian authors often quoted; from which it appeared, that Algebra was known to the Indians before it was known to the Arabians. Nothing, however, of all this is to be found in the work of Diophantus, which was published about three years after the time when Bombelli wrote. As it is, at the same time, impossible that he could be so much mistaken about a manuscript which he had particularly examined, this passage remains a mystery, which those who are curious about the ancient history of science would be very glad to have unravelled. See Hutton's *History of Algebra*.

in 1669. This ingenious author perceived a greater extent, but not yet the whole of the truth, partially discovered by Vieta, viz. the successive formation of the coefficients of an equation from the sum of the roots; the sum of their products taken two and two; the same taken three and three, &c. whether the roots be positive or negative. He appears also to have been the first who understood the use of negative roots in the solution of geometrical problems, and is the author of the figurative expression, which gives to negative quantities the name of *quantities less than nothing;* a phrase that has been severely censured by those who forget that there are correct ideas, which correct language can hardly be made to express. The same mathematician conceived the notion of imaginary roots, and showed that the number of the roots of an equation could not exceed the exponent of the highest power of the unknown quantity. He was also in possession of the very refined and difficult rule, which forms the sums of the powers of the roots of an equation from the coefficients of its terms. This is the greatest list of discoveries which the history of any algebraist could yet furnish.

The person next in order, as an inventor in Algebra, is Thomas Harriot, an English mathematician, whose book, *Artis Analyticæ Praxis,* was published after his death, in 1631. This book contains the genesis of all equations, by the continued multiplication of simple equations; that is to say, it explains the truth in its full extent, to which Vieta and Girard had been approximating. By Harriot also, the method of extracting the roots of equations was greatly improved; the smaller letters of the alphabet, instead of the capital letters employed by Vieta, were introduced; and by this improvement, trifling, indeed, compared with the rest, the form and exterior of algebraic expression were brought nearer to those which are now in use.

I have been the more careful to note very particularly the degrees by which the properties of equations were thus unfolded, because I think it forms an instance hardly paralleled in science, where a succession of able men, without going wrong, advanced, nevertheless, so slowly in the discovery of a truth which, when known, does not seem to be of a very hidden and abstruse nature. Their slow progress arose from this, that they worked with an instrument, the use of which they did not fully comprehend, and employed a language which expressed more than they were prepared to understand;—a language which, under the notion, first of negative and then of imaginary quantities, seemed to involve such mysteries as the accuracy of mathematical science must necessarily refuse to admit.

The distinguished author of whom I have just been speaking was born at Oxford in 1560. He was employed in the second expedition sent out by Sir Walter Ralegh to Vir-

ginia, and on his return published an account of that country. He afterwards devoted himself entirely to the study of the mathematics; and it appears from some of his manuscripts, lately discovered, that he observed the spots of the sun as early as December 1610, not more than a month later than Galileo. He also made observations on Jupiter's satellites, and on the comets of 1607, and of 1618.[1]

The succession of discoveries, above related, brought the algebraic analysis, abstractly considered, into a state of perfection, little short of that which it has attained at the present moment. It was thus prepared for the step which was about to be taken by Descartes, and which forms one of the most important epochas in the history of the mathematical sciences. This was the application of the algebraic analysis, to define the nature, and investigate the properties, of curve lines, and, consequently, to represent the notion of variable quantity. It is often said, that Descartes was the first who applied algebra to geometry; but this is inaccurate; for such applications had been made before, particularly by Vieta, in his treatise on angular sections. The invention just mentioned is the undisputed property of Descartes, and opened up vast fields of discovery for those who were to come after him.

The work in which this was contained is a tract of no more than 106 quarto pages; and there is probably no book of the same size which has conferred so much and so just celebrity on its author. It was first published in 1637.

In the first of the three books into which the tract just mentioned is divided, the author begins with the consideration of such geometrical problems as may be resolved by circles and straight lines; and explains the method of constructing algebraic formulas, or of translating a truth from the language of algebra into that of geometry. He then proceeds to the consideration of the problem, known among the ancients by the name of the *locus ad quatuor rectas*, and treated of by Apollonius and Pappus. The algebraic analysis afforded a method of resolving this problem in its full extent; and the consideration of it is again resumed in the second book. The thing required is, to find the locus of a point, from which, if perpendiculars be drawn to four lines given in position, a given function of these perpendiculars, in which the variable quantities are only of two dimen-

---

[1] The manuscripts which contain these observations, and probably many other things of great interest, are preserved in the collection of the Earl of Egremont, having come into the possession of his family from Henry Percy Earl of Northumberland, a most liberal patron of science, with whom Harriot appears to have chiefly lived after his return from Virginia

sions, shall be always of the same magnitude.[1] Descartes shows the locus, on this hypothesis, to be always a conic section; and he distinguishes the cases in which it is a circle, an ellipsis, a parabola, or a hyperbola. It was an instance of the most extensive investigation which had yet been undertaken in geometry, though, to render it a complete solution of the problem, much more detail was doubtless necessary. The investigation is extended to the cases where the function, which remains the same, is of three, four, or five dimensions, and where the locus is a line of a higher order, though it may, in certain circumstances, become a conic section. The lines given in position may be more than four, or than any given number; and the lines drawn to them may either be perpendiculars, or lines making given angles with them. The same analysis applies to all the cases; and this problem, therefore, afforded an excellent example of the use of algebra in the investigation of geometrical propositions. The author takes notice of the unwillingness of the ancients to transfer the language of arithmetic into geometry, so that they were forced to have recourse to very circuitous methods of expressing those relations of quantity in which powers beyond the third are introduced. Indeed, to deliver investigation from those modes of expression which involve the composition of ratios, and to substitute in their room the multiplication of the numerical measures, is of itself a very great advantage, arising from the introduction of algebra into geometry.

In this book also, an ingenious method of drawing tangents to curves is proposed by Descartes, as following from his general principles, and it is an invention with which he appears to have been particularly pleased. He says, "Nec verebor dicere problema hoc non modo eorum, quæ scio, utilissimum et generalissimum esse, sed etiam eorum quæ in geometria scire unquam desideraverim."[2] This passage is not a little characteristic of Descartes, who was very much disposed to think well of what he had done himself, and even to suppose that it could not easily be rendered more perfect. The truth, however, is, that his method of drawing tangents is extremely operose, and is one of those hasty views which, though ingenious and even profound, require to be vastly simplified, before they can be reduced to practice. Fermat, the rival and sometimes the superior of Descartes, was far more fortunate with regard to this problem, and his method of drawing tangents to curves, is the same in effect that has been followed by all the geometers since

---

[1] It will easily be perceived, that the word *function* is not contained in the original enunciation of the problem. It is a term but lately introduced into mathematical language, and affords here, as on many other occasions, a more general and more concise expression than could be otherwise obtained.

[2] Cartesii Geometria, p. 40.

his time,—while that of Descartes, which could only be valued when the other was unknown, has been long since entirely abandoned. The remainder of the second book is occupied with the consideration of the curves, which have been called the ovals of Descartes, and with some investigations concerning the centres of lenses; the whole indicating the hand of a great master, and deserving the most diligent study of those who would become acquainted with this great enlargement of mathematical science.

The third book of the geometry treats of the construction of equations by geometric curves, and it also contains a new method of resolving biquadratic equations.

The leading principles of algebra were now unfolded, and the notation was brought, from a mere contrivance for abridging common language, to a system of symbolical writing, admirably fitted to assist the mind in the exercise of thought.

The happy idea, indeed, of expressing quantity, and the operations on quantity, by conventional symbols, instead of representing the first by real magnitudes, and enunciating the second in words, could not but make a great change on the nature of mathematical investigation. The language of mathematics, whatever may be its form, must always consist of two parts; the one denoting quantities simply, and the other denoting the manner in which the quantities are combined, or the operations understood to be performed on them. Geometry expresses the first of these by real magnitudes, or by what may be called natural signs; a line by a line, an angle by an angle, an area by an area, &c.; and it describes the latter by words. Algebra, on the other hand, denotes both quantity, and the operations on quantity, by the same system of conventional symbols. Thus, in the expression $x^3 - a x^2 + b^3 = o$, the letters a, b, x, denote quantities, but the terms x^3, $a x^2$, &c. denote certain operations performed on those quantities, as well as the quantities themselves; x^3 is the quantity x raised to the cube; and ax^2 the same quantity x raised to the square, and then multiplied into a, &c.; the combination, by addition or subtraction, being also expressed by the signs + and —.

Now, it is when applied to this latter purpose that the algebraic language possesses such exclusive excellence. The mere magnitudes themselves might be represented by figures, as in geometry, as well as in any way whatever; but the operations they are to be subjected to, if described in words, must be set before the mind slowly, and in succession, so that the impression is weakened, and the clear apprehension rendered difficult. In the algebraic expression, on the other hand, so much meaning is concentrated into a narrow space, and the impression made by all the parts is so simultaneous, that nothing can be more favourable to the exertion of the reasoning powers, to the continuance of their action, and their security against error. Another advantage resulting from the use of the

same notation, consists in the reduction of all the different relations among quantities to the simplest of those relations, that of equality, and the expression of it by equations. This gives a great facility of generalization, and of comparing quantities with one another. A third arises from the substitution of the arithmetical operations of multiplication and division, for the geometrical method of the composition and resolution of ratios. Of the first of these, the idea is so clear, and the work so simple; of the second, the idea is comparatively so obscure, and the process so complex, that the substitution of the former for the latter could not but be accompanied with great advantage. This is, indeed, what constitutes the great difference in practice between the algebraic and the geometric method of treating quantity. When the quantities are of a complex nature, so as to go beyond what in algebra is called the third power, the geometrical expression is so circuitous and involved, that it renders the reasoning most laborious and intricate. The great facility of generalization in algebra, of deducing one thing from another, and of adapting the analysis to every kind of research, whether the quantities be constant or variable, finite or infinite, depends on this principle more than any other. Few of the early algebraists seem to have been aware of these advantages.

The use of the signs *plus* and *minus* has given rise to some dispute. These signs were at first used the one to denote addition, the other subtraction, and for a long time were applied to no other purpose. But as, in the multiplication of a quantity, consisting of parts connected by those signs, into another quantity similarly composed, it was always found, and could be universally demonstrated, that, in uniting the particular products of which the total was made up, those of which both the factors had the sign *minus* before them, must be added into one sum with those of which all the factors had the sign *plus;* while those of which one of the factors had the sign *plus,* and the other the sign *minus,* must be subtracted from the same,—this general rule came to be more simply expressed by saying, that in multiplication like signs gave *plus,* and that unlike signs gave *minus.*

Hence the signs *plus* and *minus* were considered, not as merely denoting the relation of one quantity to another placed before it, but, by a kind of *fiction,* they were considered as denoting qualities inherent in the quantities to the names of which they were prefixed. This fiction was found extremely useful, and it was evident that no error could arise from it. It was necessary to have a rule for determining the sign belonging to a product, from the signs of the factors composing that product, independently of every other consideration; and this was precisely the purpose for which the above fiction was introduced. So necessary is this rule in the generalizations of algebra, that we meet with it in Diophantus, notwithstanding the imperfection of the language he employed; for he states, that

Λεῖψις into Λεῖψις gives Ὕπαρξις, &c. The reduction, therefore, of the operations on quantity to an arithmetical form, necessarily involves this use of the signs *plus* or *minus*; that is, their application to denote something like absolute qualities in the objects they collect together. The attempts to free algebra from this use of the signs have of course failed, and must ever do so, if we would preserve to that science the extent and facility of its operations.

Even the most scrupulous purist in mathematical language must admit, that no real error is ever introduced by employing the signs in this most abstract sense. If the equation $x^3+px^2+qx+r=o$, be said to have one positive and two negative roots, this is certainly as exceptionable an application of the term *negative*, as any that can be proposed; yet, in reality, it means nothing but this intelligible and simple truth, that $x^3+px^2+qx+r=(x-a)(x+b)(x+c)$; or that the former of these quantities is produced by the multiplication of the three binomial factors, $x-a$, $x+b$, $x+c$. We might say the same nearly as to imaginary roots; they show that the simple factors cannot be found, but that the quadratic factors may be found; and they also point out the means of discovering them.

The aptitude of these same signs to denote contrariety of position among geometric magnitudes, makes the foregoing application of them infinitely more extensive and more indispensable.

From the same source arises the great simplicity introduced into many of the theorems and rules of the mathematical sciences. Thus, the rule for finding the latitude of a place from the sun's meridian altitude, if we employ the signs *plus* and *minus* for indicating the position of the sun and of the place relatively to the equator, is enunciated in one simple proposition, which includes every case, without any thing either complex or ambiguous. But if this is not done,—if the signs *plus* and *minus* are not employed, there must be at least two rules, one when the sun and place are on the same side of the equator, and another when they are on different sides. In the more complicated calculations of spherical trigonometry, this holds still more remarkably. When one would accommodate such rules to those who are unacquainted with the use of the algebraic signs, they are perhaps not to be expressed in less than four, or even six different propositions; whereas, if the use of these signs is supposed, the whole is comprehended in a single sentence. In such cases, it is obvious that both the memory and understanding derive great advantage from the use of the signs, and profit by a simplification, which is the work entirely of the algebraic language, and cannot be imitated by any other.

That I might not interrupt the view of improvements so closely connected with one another, I have passed over one of the discoveries, which does the greatest honour to the seventeenth century, and which took place near the beginning of it.

As the accuracy of astronomical observation had been continually advancing, it was necessary that the correctness of trigonometrical calculation, and of course its difficulty, should advance in the same proportion. The signs and tangents of angles could not be expressed with sufficient correctness without decimal fractions, extending to five or six places below unity, and when to three such numbers a fourth proportional was to be found, the work of multiplication and division became extremely laborious. Accordingly, in the end of the sixteenth century, the time and labour consumed in such calculations had become excessive, and were felt as extremely burdensome by the mathematicians and astronomers all over Europe. Napier of Merchiston, whose mind seems to have been peculiarly turned to arithmetical researches, and who was also devoted to the study of astronomy, had early sought for the means of relieving himself and others from this difficulty. He had viewed the subject in a variety of lights, and a number of ingenious devices had occurred to him, by which the tediousness of arithmetical operations might, more or less completely, be avoided. In the course of these attempts, he did not fail to observe, that whenever the numbers to be multiplied or divided were terms of a geometrical progression, the product or the quotient must also be a term of that progression, and must occupy a place in it pointed out by the places of the given numbers, so that it might be found from mere inspection, if the progression were far enough continued. If, for instance, the third term of the progression were to be multiplied by the seventh, the product must be the tenth, and if the twelfth were to be divided by the fourth, the quotient must be the eighth; so that the multiplication and division of such terms was reduced to the addition and subtraction of the numbers which indicated their places in the progression.

This observation, or one very similar to it, was made by Archimedes, and was employed by that great geometer to convey an idea of a number too vast to be correctly expressed by the arithmetical notation of the Greeks. Thus far, however, there was no difficulty, and the discovery might certainly have been made by men much inferior either to Napier or Archimedes. What remained to be done, what Archimedes did not attempt, and what Napier completely performed, involved two great difficulties. It is plain, that the resource of the geometrical progression was sufficient, when the given numbers were terms of that progression; but if they were not, it did not seem that any advantage could be derived from it. Napier, however, perceived, and it was by no means obvious, that all numbers whatsoever might be inserted in the progression, and have their places assigned in it. After conceiving the possibility of this, the next difficulty was, to discover the principle, and to execute the arithmetical process, by which these places were to be ascertained. It is in these two points that the peculiar merit of his invention consists; and at a period

when the nature of series, and when every other resource of which he could avail himself were so little known, his success argues a depth and originality of thought which, I am persuaded, have rarely been surpassed.

The way in which he satisfied himself that all numbers might be intercalated between the terms of the given progression, and by which he found the places they must occupy, was founded on a most ingenious supposition,—that of two points describing two different lines, the one with a constant velocity, and the other with a velocity always increasing in the ratio of the space the point had already gone over: the first of these would generate magnitudes in arithmetical, and the second magnitudes in geometrical progression. It is plain, that all numbers whatsoever would find their places among the magnitudes so generated; and, indeed, this view of the subject is as simple and profound as any which, after two hundred years, has yet presented itself to mathematicians. The mode of deducing the results has been simplified; but it can hardly be said that the principle has been more clearly developed.

I need not observe, that the numbers which indicate the places of the terms of the geometrical progression are called by Napier the *logarithms* of those terms.

Various systems of logarithms, it is evident, may be constructed according to the geometrical progression assumed; and of these, that which was first contrived by Napier, though the simplest, and the foundation of the rest, was not so convenient for the purposes of calculation, as one which soon afterwards occurred, both to himself and his friend Briggs, by whom the actual calculation was performed. The new system of logarithms was an improvement, practically considered; but in as far as it was connected with the principle of the invention, it is only of secondary consideration. The original tables had been also somewhat embarrassed by too close a connection between them and trigonometry. The new tables were free from this inconvenience.

It is probable, however, that the greatest inventor in science was never able to do more than to accelerate the progress of discovery, and to anticipate what time, "the author of authors," would have gradually brought to light. Though logarithms had not been invented by Napier, they would have been discovered in the progress of the algebraic analysis, when the arithmetic of powers and exponents, both integral and fractional, came to be fully understood. The idea of considering all numbers, as powers of one given number, would then have readily occurred, and the doctrine of series would have greatly facilitated the calculations which it was necessary to undertake. Napier had none of these advantages, and they were all supplied by the resources of his own mind. Indeed, as there never was any invention for which the state of knowledge had less prepared the way, there never was any where more merit fell to the share of the inventor.

His good fortune, also, not less than his great sagacity, may be remarked. Had the invention of logarithms been delayed to the end of the seventeenth century, it would have come about without effort, and would not have conferred on the author the high celebrity which Napier so justly derives from it. In another respect he has also been fortunate. Many inventions have been eclipsed or obscured by new discoveries; or they have been so altered by subsequent improvements, that their original form can hardly be recognised, and, in some instances, has been entirely forgotten. This has almost always happened to the discoveries made at an early period in the progress of science, and before their principles were fully unfolded. It has been quite otherwise with the invention of logarithms, which came out of the hands of the author so perfect, that it has never received but one material improvement, that which it derived, as has just been said, from the ingenuity of his friend in conjunction with his own. Subsequent improvements in science, instead of offering any thing that could supplant this invention, have only enlarged the circle to which its utility extended. Logarithms have been applied to numberless purposes, which were not thought of at the time of their first construction. Even the sagacity of their author did not see the immense fertility of the principle he had discovered; he calculated his tables merely to facilitate arithmetical, and chiefly trigonometrical computation, and little imagined that he was at the same time constructing a scale whereon to measure the density of the strata of the atmosphere, and the heights of mountains; that he was actually computing the areas and the lengths of innumerable curves, and was preparing for a calculus which was yet to be discovered, many of the most refined and most valuable of its resources. Of Napier, therefore, if of any man, it may safely be pronounced, that his name will never be eclipsed by any one more conspicuous, or his invention superseded by any thing more valuable.

As a geometrician, Napier has left behind him a noble monument in the two trigonometrical theorems, which are known by his name, and which appear first to have been communicated in writing to Cavalleri, who has mentioned them with great eulogy.[1] They are theorems not a little difficult, and of much use, as being particularly adapted to logarithmic calculation. They were published in the *Canon Mirificus Logarithmorum*, at Edinburgh, in 1614.[2]

[2] A reprint of the *Canon Mirificus*, from the original edition, is given in the 6th Volume of the great *Thesaurus*, in which Baron Maseres, with his usual zeal and intelligence, has collected and illustrated everything of importance that has been written on the subject of logarithms. See *Scriptores Logarithmici*, 4to. Vol. VI. p. 475.

Section II.

EXPERIMENTAL INVESTIGATION.

In this section I shall begin with a short view of the state of Physical Knowledge before the introduction of the Inductive Method; I shall next endeavour to explain that method by an analysis of the *Novum Organum;* and shall then inquire how far the principles established in that work have actually contributed to the advancement of Natural Philosophy.

1. Ancient Physics.

Though the phenomena of the material world could not but early excite the curiosity of a being who, like man, receives his strongest impressions from without, yet an accurate knowledge of those phenomena, and their laws, was not to be speedily acquired. The mere extent and variety of the objects were, indeed, such obstacles to that acquisition, as could not be surmounted but in the course of many ages. Man could not at first perceive from what point he must begin his inquiries, in what direction he must carry them on, or by what rules he must be guided. He was like a traveller going forth to explore a vast and unknown wilderness, in which a multitude of great and interesting objects presented themselves on every side, while there was no path for him to follow, no rule to direct his survey, and where the art of observing, and the instruments of observation, must equally be the work of his own invention. In these circumstances, the selection of the objects to be studied was the effect of instinct rather than of reason, or of the passions and emotions, more than of the understanding. When things new and unlike those which occurred in the course of every day's experience presented themselves, they excited wonder or surprise, and created an anxiety to discover some principle which might connect them with the appearances commonly observed. About these last, men felt no desire to be farther informed; but when the common order of things was violated, and something new or singular was produced, they began to examine into the fact, and attempted to inquire into the cause. Nobody sought to know why a stone fell to the ground, why smoke ascended, or why the stars revolved round the earth. But if a fiery meteor shot across the heavens, —if the flames of a volcano burst forth,—or if an earthquake shook the foundations of the

world, terror and curiosity were both awakened ; and when the former emotion had subsided, the latter was sure to become active. Thus, to trace a resemblance between the events with which the observer was most familiar, and those to which he was less accustomed, and which had excited his wonder, was the first object of inquiry, and produced the first advances towards generalization and philosophy. [1]

This principle, which it were easy to trace, from tribes the most rude and barbarous, to nations the most highly refined, was what yielded the first attempts toward classification and arrangement, and enabled man, out of individuals, subject to perpetual change, to form certain fixed and permanent objects of knowledge,—the species, genera, orders, and classes, into which he has distributed these individuals. By this effort of mental abstraction, he has created to himself a new and intellectual world, free from those changes and vicissitudes to which all material things are destined. This, too, is a work not peculiar to the philosopher, but, in a certain degree, is performed by every man who compares one thing with another, and who employs the terms of ordinary language.

Another great branch of knowledge is occupied, not about the mere arrangement and classification of objects, but about events or changes, the laws which those changes observe, and the causes by which they are produced. In a science, which treated of events and of change, the nature and properties of motion came of course to be studied, and the ancient philosophers naturally enough began their inquiries with the definition of motion, or the determination of that in which it consists. Aristotle's definition is highly characteristical of the vagueness and obscurity of his physical speculations. He calls motion " the act of a being in power, as far as in power,"—words to which it is impossible that any distinct idea can ever have been annexed.

The truth is, however, that the best definition of motion can be of very little service in physics. Epicurus defined it to be the " change of place," which is, no doubt, the simplest and best definition that can be given ; but it must, at the same time, be confessed, that neither he nor the moderns who have retained his definition, have derived the least advantage from it in their subsequent researches. The properties, or, as they are called, the laws of motion, cannot be derived from mere definition ; they must be sought for in ex-

---

Dell 'ignoranza é la figlia,
E del sapere
La madre.

perience and observation, and are not to be found without a diligent comparison, and scrupulous examination of facts. Of such an examination, neither Aristotle, nor any other of the ancients, ever conceived the necessity, and hence those laws remained quite unknown throughout all antiquity.

When the laws of motion were unknown, the other parts of natural philosophy could make no great advances. Instead of conceiving that there resides in *body* a natural and universal tendency to persevere in the same state, whether of rest, or of motion, they believed that terrestrial bodies tended *naturally* either to fall to the ground, or to ascend from it, till they attained their own place; but that, if they were impelled by an oblique force, then their motion became *unnatural* or *violent*, and tended continually to decay. With the heavenly bodies, again, the natural motion was circular and uniform, eternal in its course, but perpetually varying in its direction. Thus, by the distinction between natural and violent motion among the bodies of the earth, and the distinction between what we may call the laws of motion in terrestrial and celestial bodies, the ancients threw into all their reasonings upon this fundamental subject a confusion and perplexity, from which their philosophy never was delivered.

There was, however, one part of physical knowledge in which their endeavours were attended with much better success, and in which they made important discoveries. This was in the branch of Mechanics, which treats of the action of forces *in equilibrio*, and producing not motion but rest;—a subject which may be understood, though the laws of motion are unknown.

The first writer on this subject is Archimedes. He treated of the lever, and of the centre of gravity, and has shown that there will be an equilibrium between two heavy bodies connected by an inflexible rod or lever, when the point in which the lever is supported is so placed between the bodies, that their distances from it are inversely as their weights. Great ingenuity is displayed in this demonstration; and it is remarkable, that the author borrows no principle from experiment, but establishes his conclusion entirely by reasoning *a priori*. He assumes, indeed, that equal bodies, at the ends of the equal arms of a lever, will balance one another; and also, that a cylinder, or parallelopiped of homogeneous matter, will be balanced about its centre of magnitude. These, however, are not inferences from experience; they are, properly speaking, conclusions deduced from the principle of the *sufficient reason*.

The same great geometer gave a beginning to the science of Hydrostatics, and discovered the law which determines the loss of weight sustained by a body on being immersed in

water, or in any other fluid. His demonstration rests on a principle, which he lays down as a postulatum, that, in water, the parts which are less pressed are always ready to yield in any direction to those that are more pressed, and from this, by the application of mathematical reasoning, the whole theory of floating bodies is derived. The above is the same principle on which the modern writers on hydrostatics proceed ; they give it not as a postulatum, but as constituting the definition of a fluid.

Archimedes, therefore, is the person who first made the application of mathematics to natural philosophy. No individual, perhaps, ever laid the foundation of more great discoveries than that geometer, of whom Wallis has said with so much truth, " Vir stupendæ sagacitatis, qui prima fundamenta posuit inventionum feré omnium in quibus promovendis ætas nostra gloriatur."

The mechanical inquiries, begun by the geometer of Syracuse, were extended by Ctesibius and Hero ; by Anthemius of Tralles ; and, lastly, by Pappus Alexandrinus. Ctesibius and Hero were the first who analyzed mechanical engines, reducing them all to combinations of five simple mechanical contrivances, to which they gave the name of Δυναμεις, or Powers, the same which they retain at the present moment.

Even in mechanics, however, the success of these investigations was limited ; and failed in those cases where the resolution of forces is necessary, that principle being then entirely unknown. Hence the force necessary to sustain a body on an inclined plane, is incorrectly determined by Pappus, and serves to mark a point to which the mechanical theories of antiquity did not extend.

In another department of physical knowledge, Astronomy, the endeavours of the ancients were also accompanied with success. I do not here speak of their astronomical theories, which were, indeed, very defective, but of their discovery of the apparent motions of the heavenly bodies, from the observations begun by Hipparchus, and continued by Ptolemy. In this their success was great ; and while the earth was supposed to be at rest, and while the instruments of observation had but a very limited degree of accuracy, a nearer approach to the truth was probably not within the power of human ingenuity. Mathematical reasoning was very skilfully applied, and no men whatever, in the same circumstances, are likely to have performed more than the ancient astronomers. They succeeded, because they were observers, and examined carefully the motions which they treated of. The philosophers, again, who studied the motion of terrestrial bodies, either did not observe at all, or observed so slightly, that they could obtain no accurate knowledge, and in general they knew just enough of the facts to be misled by them.

The opposite ways which the ancients thus took to study the Heavens and the Earth, observing the one, and dreaming, as one may say, over the other, though a striking inconsistency, is not difficult to be explained.

No information at all could be obtained in astronomy, without regular and assiduous observation, and without instruments capable of measuring angles, and of measuring time, either directly or indirectly. The steadiness and regularity of the celestial motions seemed to invite the most scrupulous attention. On the other hand, as terrestrial objects were always at hand, and spontaneously falling under men's view, it seemed unnecessary to take much trouble to become acquainted with them, and as for applying measures, their irregularity appeared to render every idea of such proceeding nugatory. The Aristotelian philosophy particularly favoured this prejudice, by representing the earth, and all things on its surface, as full of irregularity and confusion, while the principles of heat and cold, dryness and moisture, were in a state of perpetual warfare. The unfortunate division of motion into natural and violent, and the distinction, still more unfortunate, between the properties of motion and of body, in the heavens and on the earth, prevented all intercourse between the astronomer and the naturalist, and all transference of the maxims of the one to the speculations of the other.

Though, on account of this inattention to experiment, nothing like the true system of natural philosophy was known to the ancients, there are, nevertheless, to be found in their writings many brilliant conceptions, several fortunate conjectures, and gleams of the light which was afterwards to be so generally diffused.

Anaxagoras and Empedocles, for example, taught that the moon shines by light borrowed from the sun, and were led to that opinion, not only from the phases of the moon, but from its light being weak, and unaccompanied by heat. That it was a habitable body, like the earth, appears to be a doctrine as old as Orpheus; some lines, ascribed to that poet, representing the moon as an earth, with mountains and cities on its surface.

Democritus supposed the spots on the face of the moon to arise from the inequalities of the surface, and from the shadows of the more elevated parts projected on the plains. Every one knows how conformable this is to the discoveries made by the telescope.

Plutarch considers the velocity of the moon's motion as the cause which prevents that body from falling to the earth, just as the motion of a stone in a sling prevents it from falling to the ground. The comparison is, in a certain degree, just, and clearly implies the notion of centrifugal force; and gravity may also be considered as pointed at for the cause which gives the moon a tendency to the earth. Here, therefore, a foundation was

laid for the true philosophy of the celestial motions; but it was laid without effect. It was merely the conjecture of an ingenious mind, wandering through the regions of possibility, guided by no evidence, and having no principle which could give stability to its opinions. Democritus, and the authors of that physical system which Lucretius has so beautifully illustrated, were still more fortunate in some of their conjectures. They taught that the Milky Way is the light of a great number of small stars, very close to one another; a magnificent conception, which the latest improvements of the telescope have fully verified. Yet, as if to convince us that they derived this knowledge from no pure or certain source, the same philosophers maintained, that the sun and the moon are bodies no larger than they appear to us to be.

Very just notions concerning comets were entertained by some of the ancients. The Chaldeans considered those bodies as belonging to the same order with the planets; and this was also the opinion of Anaxagoras, Pythagoras, and Democritus. The remark of Seneca on this subject is truly philosophical, and contains a prediction which has been fully accomplished: "Why do we wonder that comets, which are so rare a spectacle in the world, observe laws which to us are yet unknown, and that the beginning and end of motions, so seldom observed, are not yet fully understood?"—*Veniet tempus, quo ista quæ nunc latent, in lucem dies extrahat, et longioris ævi diligentia: ad inquisitionem tantorum ætas una non sufficit. Veniet tempus, quo posteri nostri tam aperta nos nescisse mirentur.*[1]

It was, however, often the fate of such truths to give way to error. The comets, which these ancient philosophers had ranked so justly with the stars, were degraded by Aristotle into meteors floating in the earth's atmosphere; and this was the opinion concerning them which ultimately prevailed.

But, notwithstanding the above, and a few other splendid conceptions which shine through the obscurity of the ancient physics, the system, taken on the whole, was full of error and inconsistency. Truth and falsehood met almost on terms of equality; the former separated from its root, experience, found no preference above the latter; to the latter, in fact, it was generally forced to give way, and the dominion of error was finally established.

One ought to listen, therefore, with caution to the encomiums sometimes bestowed on the philosophy of those early ages. If these encomiums respected only the talents, the

---

[1] Nat. Quæst. Lib. vii. c. 25.

genius, the taste of the great masters of antiquity, we would subscribe to them without any apprehension of going beyond the truth. But if they extend to the methods of philosophizing, and the discoveries actually made, we must be excused for entering our dissent, and exchanging the language of panegyric for that of apology. The infancy of science could not be the time when its attainments were the highest; and, before we suffer ourselves to be guided by the veneration of antiquity, we ought to consider in what real antiquity consists. With regard to the progress of knowledge and improvement, "*we* are more ancient than those who went before us."[1] The human race has now more experience than in the generations that are past, and of course may be expected to have made higher attainments in science and philosophy. Compared with natural philosophy, as it now exists, the ancient physics are rude and imperfect. The speculations contained in them are vague and unsatisfactory, and of little value, but as they elucidate the history of the errors and illusions to which the human mind is subject. Science was not merely stationary, but often retrograde; the earliest opinions were frequently the best; and the reasonings of Democritus and Anaxagoras were in many instances more solid than those of Plato and Aristotle. Extreme credulity disgraced the speculations of men who, however ingenious, were little acquainted with the laws of nature, and unprovided with the great criterion by which the evidence of testimony can alone be examined. Though observations were sometimes made, experiments were never instituted; and philosophers, who were little attentive to the facts which spontaneously offered, did not seek to increase their number by artificial combinations. Experience, in those ages, was a light which darted a few tremulous and uncertain rays on some small portions of the field of science, but men had not acquired the power over that light which now enables them to concentrate its beams, and to fix them steadily on whatever object they wish to examine. This power is what distinguishes the modern physics, and is the cause why later philosophers, without being more ingenious than their predecessors, have been infinitely more successful in the study of nature.

2. Novum Organum.

The defects which have been ascribed to the ancient physics were not likely to be corrected in the course of the middle ages. It is true, that, during those ages, a science of pure

---

[1] Bacon.

experiment had made its appearance in the world, and might have been expected to remedy the greatest of these defects, by turning the attention of philosophers to experience and observation. This effect, however, was far from being immediately produced; and none who professed to be in search of truth ever wandered over the regions of fancy, in paths more devious and eccentric, than the first experimenters in chemistry. They had become acquainted with a series of facts so unlike to any thing already known, that the ordinary principles of belief were shaken or subverted, and the mind laid open to a degree of credulity far beyond any with which the philosophers of antiquity could be reproached. An unlooked-for extension of human power had taken place; its limits were yet unknown; and the boundary between the possible and the impossible was no longer to be distinguished. The adventurers in an unexplored country, given up to the guidance of imagination, pursued objects which the kindness, no less than the wisdom of nature, have rendered unattainable by man; and in their speculations peopled the air, the earth, and all the elements, with spirits and genii, the invisible agents destined to connect together all the facts which they knew, and all those which they hoped to discover. Chemistry, in this state, might be said to have an elective attraction for all that was most absurd and extravagant in the other parts of knowledge; alchemy was its immediate offspring, and it allied itself in succession with the dreams of the Cabbalists, the Rosicrucians, and the Theosophers. Thus a science, founded in experiment, and destined one day to afford such noble examples of its use, exhibited for several ages little else than a series of illusory pursuits, or visionary speculations, while now and then a fact was accidentally discovered.

Under the influence of these circumstances arose Paracelsus, Van Helmont, Fludde, Cardan, and several others, conspicuous no less for the weakness than the force of their understandings: men who united extreme credulity, the most extravagant pretensions, and the most excessive vanity, with considerable powers of invention, a complete contempt for authority, and a desire to consult experience; but destitute of the judgment, patience, and comprehensive views, without which the responses of that oracle are never to be understood. Though they appealed to experience, and disclaimed subjection to the old legislators of science, they were in too great haste to become legislators themselves, and to deduce an explanation of the whole phenomena of nature from a few facts, observed without accuracy, arranged without skill, and never compared or confronted with one another. Fortunately, however, from the turn which their inquiries had taken, the ill done by them has passed away, and the good has become permanent. The reveries of Paracelsus have disappeared, but his application of chemistry to pharmacy has conferred a lasting benefit on the

world. The *Archæus* of Van Helmont, and the army of spiritual agents with which the discovery of elastic fluids had filled the imagination of that celebrated empiric, are laughed at, or forgotten; but the fluids which he had the sagacity to distinguish, form, at the present moment, the connecting principles of the new chemistry.

Earlier than any of the authors just named, but in a great measure under the influence of the same delusions, Roger Bacon appears to have been more fully aware than any of them of the use of experiment, and of mathematical reasoning, in physical and mechanical inquiries. But, in the thirteenth century, an appeal from the authority of the schools, even to nature herself, could not be made with impunity. Bacon, accordingly, incurred the displeasure both of the University and of the Church, and this forms one of his claims to the respect of posterity, as it is but fair to consider persecution inflicted by the ignorant and bigoted as equivalent to praise bestowed by the liberal and enlightened.

Much more recently, Gilbert, in his treatise on the Magnet, had given an example of an experimental inquiry, carried on with more correctness, and more enlarged views, than had been done by any of his predecessors. Nevertheless, in the end of the sixteenth century, it might still be affirmed, that the situation of the great avenue to knowledge was fully understood by none, and that its existence, to the bulk of philosophers, was utterly unknown.

It was about this time that Francis Bacon (Lord Verulam) began to turn his powerful and creative mind to contemplate the state of human knowledge, to mark its imperfections, and to plan its improvement. One of the considerations which appears to have impressed his mind most forcibly, was the vagueness and uncertainty of all the physical speculations then existing, and the entire want of connection between the sciences and the arts.

Though these two things are in their nature so closely united, that the same truth which is a principle in science, becomes a rule in art, yet there was at that time hardly any practical improvement which had arisen from a theoretical discovery. The natural alliance between the knowledge and the power of man seemed entirely interrupted; nothing was to be seen of the mutual support which they ought to afford to one another; the improvement of art was left to the slow and precarious operation of chance, and that of science to the collision of opposite opinions.

"But whence," said Bacon, "can arise such vagueness and sterility in all the physical systems which have hitherto existed in the world? It is not certainly from any thing in nature itself; for the steadiness and regularity of the laws by which it is governed clearly

mark them out as objects of certain and precise knowledge. Neither can it arise from any want of ability in those who have pursued such inquiries, many of whom have been men of the highest talent and genius of the ages in which they lived; and it can, therefore, arise from nothing else but the perverseness and insufficiency of the methods that have been pursued. Men have sought to make a world from their own conceptions, and to draw from their own minds all the materials which they employed; but if, instead of doing so, they had consulted experience and observation, they would have had facts, and not opinions, to reason about, and might have ultimately arrived at the knowledge of the laws which govern the material world."

"As things are at present conducted," he adds, "a sudden transition is made from sensible objects and particular facts to general propositions, which are accounted principles, and round which, as round so many fixed poles, disputation and argument continually revolve. From the propositions thus hastily assumed, all things are derived, by a process compendious and precipitate, ill suited to discovery, but wonderfully accommodated to debate. The way that promises success is the reverse of this. It requires that we should generalize slowly, going from particular things to those that are but one step more general; from those to others of still greater extent, and so on to such as are universal. By such means, we may hope to arrive at principles, not vague and obscure, but luminous and well-defined, such as nature herself will not refuse to acknowledge."

Before laying down the rules to be observed in this inductive process, Bacon proceeds to enumerate the causes of error,—the *Idols*, as he terms them, in his figurative language, or false divinities to which the mind had so long been accustomed to bow. He considered this enumeration as the more necessary, that the same idols were likely to return, even after the reformation of science, and to avail themselves of the real discoveries that might have been made, for giving a colour to their deceptions.

These idols he divides into four classes, to which he gives names, fantastical, no doubt, but, at the same time, abundantly significant.

Idola Tribus,	Idols of the Tribe,
—— Specus,	—— of the Den,
—— Fori,	—— of the Forum,
—— Theatri,	—— of the Theatre.

1. The *idols of the tribe*, or of the race, are the causes of error founded on human nature in general, or on principles common to all mankind. "The mind," he observes, "is not like a plain mirror, which reflects the images of things exactly as they are; it is like

a mirror of an uneven surface, which combines its own figure with the figures of the objects it represents." [1]

Among the idols of this class, we may reckon the propensity which there is in all men to find in nature a greater degree of order, simplicity, and regularity, than is actually indicated by observation. Thus, as soon as men perceived the orbits of the planets to return into themselves, they immediately supposed them to be perfect circles, and the motion in those circles to be uniform; and to these hypotheses, so rashly and gratuitously assumed, the astronomers and mathematicians of all antiquity laboured incessantly to reconcile their observations.

The propensity which Bacon has here characterized so well, is the same that has been, since his time, known by the name of the *spirit of system*. The prediction, that the sources of error would return, and were likely to infest science in its most flourishing condition, has been fully verified with respect to this illusion, and in the case of sciences which had no existence at the time when Bacon wrote. When it was ascertained, by observation, that a considerable part of the earth's surface consists of minerals, disposed in horizontal strata, it was immediately concluded, that the whole exterior crust of the earth is composed, or has been composed, of such strata, continued all round without interruption; and on this, as on a certain and general fact, entire theories of the earth have been constructed.

There is no greater enemy which science has to struggle with than this propensity of the mind; and it is a struggle from which science is never likely to be entirely relieved; because, unfortunately, the illusion is founded on the same principle from which our love of knowledge takes its rise.

2. The *idols of the den* are those that spring from the peculiar character of the individual. Besides the causes of error which are common to all mankind, each individual, according to Bacon, has his own dark cavern or den, into which the light is imperfectly admitted, and in the obscurity of which a tutelary idol lurks, at whose shrine the truth is often sacrificed.

One great and radical distinction in the capacities of men is derived from this, that some minds are best adapted to mark the differences, others to catch the resemblances, of things. Steady and profound understandings are disposed to attend carefully, to proceed slowly, and to examine the most minute differences; while those that are sublime

---

[1] Novum Organum, Lib. i. Aph. 41.

and active are ready to lay hold of the slightest resemblances. Each of these easily runs into excess; the one by catching continually at distinctions, the other at affinities.

The studies, also, to which a man is addicted, have a great effect in influencing his opinions. Bacon complains, that the chemists of his time, from a few experiments with the furnace and the crucible, thought that they were furnished with principles sufficient to explain the structure of the universe; and he censures Aristotle for having depraved his physics so much with his dialectics, as to render the former entirely a science of words and controversy. In like manner, he blames a philosopher of his own age, Gilbert, who had studied magnetism to good purpose, for having proceeded to form out of it a general system of philosophy. Such things have occurred in every period of science. Thus electricity has been applied to explain the motion of the heavenly bodies; and, of late, galvanism and electricity together have been held out as explaining, not only the affinities of chemistry, but the phenomena of gravitation, and the laws of vegetable and animal life. It were a good caution for a man who studies nature, to distrust those things with which he is particularly conversant, and which he is accustomed to contemplate with pleasure.

3. The *idols of the forum* are those that arise out of the commerce or intercourse of society, and especially from language, or the means by which men communicate their thoughts to one another.

Men believe that their thoughts govern their words; but it also happens, by a certain kind of reaction, that their words frequently govern their thoughts. This is the more pernicious, that words, being generally the work of the multitude, divide things according to the lines most conspicuous to vulgar apprehensions. Hence, when words are examined, few instances are found in which, if at all abstract, they convey ideas tolerably precise and well defined. For such imperfections there seems to be no remedy, but by having recourse to particular instances, and diligently comparing the meanings of words with the external archetypes from which they are derived.

4. The *idols of the theatre* are the last, and are the deceptions which have taken their rise from the systems or dogmas of the different schools of philosophy. In the opinion of Bacon, as many of these systems as had been invented, so many representations of imaginary worlds had been brought upon the stage. Hence the name of *idola theatri.* They do not enter the mind imperceptibly like the other three; a man must labour to acquire them, and they are often the result of great learning and study.

" Philosophy," said he, " as hitherto pursued, has taken much from a few things, or a little from a great many; and, in both cases, has too narrow a basis to be of much dura-

tion or utility." The Aristotelian philosophy is of the latter kind; it has taken its principles from common experience, but without due attention to the evidence or the precise nature of the facts; the philosopher is left to work out the rest from his own invention. Of this kind, called by Bacon the *sophistical,* were almost all the physical systems of antiquity.

When philosophy takes all its principles from a few facts, he calls it *empirical,*—such as was that of Gilbert, and of the chemists.

It should be observed, that Bacon does not charge the physics of antiquity with being absolutely regardless of experiment. No system, indeed, however fantastical, has ever existed, to which that reproach could be applied in its full extent; because, without some regard to fact, no theory can ever become in the least degree plausible. The fault lies not, therefore, in the absolute rejection of experience, but in the unskilful use of it; in taking up principles lightly from an inaccurate and careless observation of many things; or, if the observations have been more accurate, from those made on a few facts, unwarrantably generalized.

Bacon proceeds to point out the circumstances, in the history of the world, which had hitherto favoured these perverse modes of philosophizing. He observes, that the periods during which science had been cultivated were not many, nor of long duration. They might be reduced to three; the first with the Greeks; the second with the Romans; and the third with the western nations, after the revival of letters. In none of all these periods had much attention been paid to natural philosophy, the great parent of the sciences.

With the Greeks, the time was very short during which physical science flourished in any degree. The seven Sages, with the exception of Thales, applied themselves entirely to morals and politics; and in later times, after Socrates had brought down philosophy from the heavens to the earth, the study of nature was generally abandoned. In the Roman republic, the knowledge most cultivated, as might be expected among a martial and ambitious people, was such as had a direct reference to war and politics. During the empire, the introduction and establishment of the Christian religion drew the attention of men to theological studies, and the important interests which were then at stake left but a small share of talent and ability to be occupied in inferior pursuits. The corruptions which followed, and the vast hierarchy which assumed the command both of the sword and the sceptre, while it occupied and enslaved the minds of men, looked with suspicion on sciences which could not easily be subjected to its control.

At the time, therefore, when Bacon wrote, it might truly be said, that a small portion

even of the learned ages, and of the abilities of learned men, had been dedicated to the study of Natural Philosophy. This served, in his opinion, to account for the imperfect state in which he found human knowledge in general; for he thought it certain, that no part of knowledge could attain much excellence without having its foundation laid in physical science.

He goes on to observe, that the end and object of knowledge had been very generally mistaken; that many, instead of seeking through it to improve the condition of human life, by new inventions and new resources, had aimed only at popular applause, and had satisfied themselves with the knowledge of words more than of things: while others, who were exceptions to this rule, had gone still farther wrong, by directing their pursuits to objects imaginary and unattainable. The alchemists, for example, alternately the dupes of their own credulity and of their own imposture, had amazed and tormented the world with hopes which were never to be realized. Others, if possible more visionary, had promised to prolong life, to extinguish disease and infirmity, and to give man a command over the world of spirits, by means of mystic incantations. "All this," says he, "is the mere boasting of ignorance; for, when the knowledge of nature shall be rightly pursued, it will lead to discoveries that will as far excel the pretended powers of magic, as the real exploits of Cæsar and Alexander exceed the fabulous adventures of Arthur of Britain, or Amadis of Gaul."[1]

Again, the reverence for antiquity, and the authority of great names, have contributed much to retard the progress of science. Indeed, the notion of antiquity which men have taken up seems to be erroneous and inconsistent. It is the duration of the world, or of the human race, as reckoned from the extremity that is past, and not from the point of time which is present, that constitutes the true antiquity to which the advancement of science may be conceived to bear some proportion; and just as we expect more wisdom and experience in an old than in a young man, we may expect more knowledge of nature from the present than from any of the ages that are past.

"It is not to be esteemed a small matter in this estimate, that, by the voyages and travels of these later times, so much more of nature has been discovered than was known at any former period. It would, indeed, be disgraceful to mankind, if, after such tracts of the material world have been laid open, which were unknown in former times,—so many seas traversed,—so many countries explored,—so many stars discovered,—that philosophy, or the intelligible world, should be circumscribed by the same boundaries as before."

---

[1] Nov. Org. Lib. i. Aph. 87.

Another cause has greatly obstructed the progress of philosophy, viz. that men inquire only into the causes of rare, extraordinary, and great phenomena, without troubling themselves about the explanation of such as are common, and make a part of the general course of nature.[1] It is, however, certain, that no judgment can be formed concerning the extraordinary and singular phenomena of nature, without comparing them with those that are ordinary and frequent.

The laws which are every day in action, are those which it is most important for us to understand; and this is well illustrated by what has happened in the scientific world since the time when Bacon wrote. The simple falling of a stone to the ground has been found to involve principles which are the basis of all we know in mechanical philosophy. Without accurate experiments on the descent of bodies at the surface of the earth, the objections against the earth's motion could not have been answered, the inertia of body would have remained unknown, and the nature of the force which retains the planets in their orbits could never have been investigated. Nothing, therefore, can be more out of its place than the fastidiousness of those philosophers, who suppose things to be unworthy of study, because, with respect to ordinary life, they are trivial and unimportant. It is an error of the same sort which leads men to consider experiment, and the actual application of the hands, as unworthy of them, and unbecoming of the dignity of science. "There are some," says Bacon, "who, delighting in mere contemplation, are offended with our frequent reference to experiments and operations to be performed by the hand, things which appear to them mean and mechanical; but these men do in fact oppose the attainment of the object they profess to pursue, since the exercise of contemplation, and the construction and invention of experiments, are supported on the same principles, and perfected by the same means."[2]

After these preliminary discussions, the great restorer of philosophy proceeds, in the second book of the Novum Organum, to describe and exemplify the nature of the induction, which he deems essential to the right interpretation of nature.

The first object must be to prepare a history of the phenomena to be explained, in all their modifications and varieties. This history is to comprehend not only all such facts as spontaneously offer themselves, but all the experiments instituted for the sake of discovery, or for any of the purposes of the useful arts. It ought to be composed with great care; the facts accurately related, and distinctly arranged; their authenticity diligently examin-

---

[1] Ibid. Aph. 119.

[2] Impetus Phil. p. 681. Note C.

ed; those that rest on doubtful evidence, though not rejected, being noted as uncertain, with the grounds of the judgment so formed. This last is very necessary; for facts often appear incredible, only because we are ill informed, and cease to appear marvellous, when our knowledge is farther extended.

All such facts, however, as appear contrary to the ordinary course of our experience, though thus noted down and preserved, must have no weight allowed them in the first steps of investigation, and are to be used only when the general principle, as it emerges from the inductive process, serves to increase their probability.

This record of facts is what Bacon calls natural history, and it is material to take notice of the comprehensive sense in which that term is understood through all his writings. According to the arrangement of the sciences, which he has explained in his treatise on the advancement of knowledge, all learning is classed relatively to the three intellectual faculties of Memory, Reason, and Imagination. Under the first of these divisions is contained all that is merely Narration or History, of whatever kind it may be. Under the second are contained the different sciences, whether they respect the Intellectual or the Material world. Under the third are comprehended Poetry and the Fine Arts. It is with the first of these classes only that we are at present concerned. The two first divisions of it are Sacred and Civil History, the meaning of which is sufficiently understood. The third division is Natural History, which comprehends the description of the facts relative to inanimate matter, and to all animals, except man. Natural history is again subdivided into three parts: 1. The history of the phenomena of nature, which are uniform; 2. Of the facts which are anomalous or extraordinary; 3. Of the processes in the different arts.

We are not to wonder at finding the processes of the arts thus enrolled among the materials of natural history. The powers which act in the processes of nature and in those of art are precisely the same, and are only directed, in the latter case, by the intention of man, toward particular objects. In art, as Bacon elsewhere observes, man does nothing more than bring things nearer to one another, or carry them farther off; the rest is performed by nature, and, on most occasions, by means of which we are quite ignorant.

Thus, when a man fires a pistol, he does nothing but make a piece of flint approach a plate of hardened steel, with a certain velocity. It is nature that does the rest;—that makes the small red hot and fluid globules of steel, which the flint had struck off, communicate their fire to the gunpowder, and, by a process but little understood, set loose the elastic fluid contained in it; so that an explosion is produced, and the ball propelled with

astonishing velocity. It is obvious that, in this instance, art only gives certain powers of nature a particular direction.

To the rules which have been given from Bacon, for the composition of natural history, I may be permitted to add this other,—that theoretical language should, as much as possible, be avoided. Appearances ought to be described in terms which involve no opinion with respect to their causes. These last are the objects of separate examination, and will be best understood if the facts are given fairly, without any dependence on what should yet be considered as unknown. This rule is very essential where the facts are in a certain degree complicated; for it is then much easier to describe with a reference to theory than without it. It is only from a skilful physician that you can expect a description of a disease which is not full of opinions concerning its cause. A similar observation might be made with respect to agriculture; and with respect to no science more than geology.

The natural history of any phenomenon, or class of phenomena, being thus prepared, the next object is, by a comparison of the different facts, to find out the cause of the phenomenon, its *form*, in the language of Bacon, or its essence. The form of any quality in body is something convertible with that quality; that is, where it exists, the quality is present, and where the quality is present, the form must be so likewise. Thus, if transparency in bodies be the thing inquired after, the form of it is something that, wherever it is found, there is transparency; and, *vice versa*, wherever there is transparency, that which we have called the form is likewise present.

The form, then, differs in nothing from the cause; only we apply the word cause where it is event or change that is the effect. When the effect or result is a permanent quality, we speak of the form or essence.

Two other objects, subordinate to *forms*, but often essential to the knowledge of them, are also occasionally subjects of investigation. These are the latent process, and the latent schematism; *latens processus, et latens schematismus*. The former is the secret and invisible progress by which sensible changes are brought about, and seems, in Bacon's acceptation, to involve the principle, since called the *law of continuity*, according to which, no change, however small, can be effected but in *time*. To know the relation between the time and the change effected in it, would be to have a perfect knowledge of the latent process. In the firing of a cannon, for example, the succession of events during the short interval between the application of the match and the expulsion of the ball, constitutes a latent process of a very remarkable and complicated nature, which, however, we can now trace with some degree of accuracy. In mechanical operations, we can often follow this process still more completely. When motion is communicated from any body to another,

it is distributed through all the parts of that other, by a law quite beyond the reach of sense to perceive directly, but yet subject to investigation, and determined by a principle, which, though late of being discovered, is now generally recognised. The applications of this mechanical principle are perhaps the instances in which a latent, and, indeed, a very recondite process, has been most completely analyzed.

The latent schematism is that invisible structure of bodies, on which so many of their properties depend. When we inquire into the constitution of crystals, or into the internal structure of plants, &c. we are examining into the latent schematism. We do the same when we attempt to explain elasticity, magnetism, gravitation, &c. by any peculiar structure of bodies, or any arrangement of the particles of matter.[1]

In order to inquire into the *form* or cause of any thing by induction, having brought together the facts, we are to begin with considering what things are thereby excluded from the number of possible forms. This exclusion is the first part of the process of induction: it confines the field of hypothesis, and brings the true explanation within narrower limits. Thus, if we were inquiring into the quality which is the cause of transparency in bodies; from the fact that the diamond is transparent, we immediately exclude rarity or porosity as well as fluidity from those causes, the diamond being a very solid and dense body.

Negative instances, or those where the given *form* is wanting, are also to be collected.

That glass, when pounded, is not transparent, is a negative fact, and of considerable importance when the *form* of transparency is inquired into; also, that collections of vapour, such as clouds and fogs, have not transparency, are negative facts of the same kind. The facts thus collected, both affirmative and negative, may, for the sake of reference, be reduced into tables.

Bacon exemplifies his method on the subject of Heat; and, though his collection of facts be imperfect, his method of treating them is extremely judicious, and the whole disquisition highly interesting.[2] He here proposes, as an experiment, to try the reflection of the heat of opaque bodies.[3] He mentions also the *vitrum calendare*, or thermometer, which was just then coming into use. His reflections, after finishing his enumeration of facts, show how sensible he was of the imperfect state of his own knowledge.[4]

After a great number of exclusions have left but a few principles, common to every case,

---

[1] Nov. Org. Lib. ii. Aph. 5, 6, &c.
[2] Ibid. Aph. 18, 20, &c.
[3] Ibid. Aph. 11.
[4] Ibid. Aph. 14.

one of these is to be assumed as the cause ; and, by reasoning from it synthetically, we are to try if it will account for the phenomena.

So necessary did this exclusive process appear to Bacon, that he says, " It may perhaps be competent to angels, or superior intelligences, to determine the form or essence directly, by affirmations from the first consideration of the subject. But it is certainly beyond the power of man, to whom it is only given to proceed at first by negatives, and, in the last place, to end in an *affirmative*, after the exclusion of every thing else."[1]

The method of induction, as laid down here, is to be considered as applicable to all investigations where experience is the guide, whether in the moral or natural world. " Some may doubt whether we propose to apply our method of investigation to natural philosophy only, or to other sciences, such as logic, ethics, politics. We answer, that we mean it to be so applied. And as the common logic, which proceeds by the syllogism, belongs not only to natural philosophy, but to all the sciences, so our logic, which proceeds by induction, embraces every thing."[2]

Though this process had been pursued by a person of much inferior penetration and sagacity to Bacon, he could not but have discovered that all facts, even supposing them truly and accurately recorded, are not of equal value in the discovery of truth. Some of them show the thing sought for in its highest degree, some in its lowest ; some exhibit it simple and uncombined, in others it appears confused with a variety of circumstances. Some facts are easily interpreted, others are very obscure, and are understood only in consequence of the light thrown on them by the former. This led our author to consider what he calls *Prerogativæ Instantiarum*, the comparative value of facts as means of discovery, or as instruments of investigation. He enumerates twenty-seven different species, and enters at some length into the peculiar properties of each. I must content myself, in this sketch, with describing a few of the most important, subjoining, as illustrations, sometimes the examples which the author himself has given, but more frequently such as have been furnished by later discoveries in science.

I. The first place in this classification is assigned to what are called *instantiæ solitariæ*, which are either examples of the same quality existing in two bodies, which have nothing in common but that quality, or of a quality differing in two bodies, which are in all other respects the same. In the first instance, the bodies differ in all things but one ; in the second, they agree in all but one. The *hypotheses* that in either case can be entertained,

---

[1] Nov. Org. Lib. ii. Aph. 15.

[2] Ibid. Lib. i. Aph. 127.

concerning the cause or *form* of the said quality, are reduced to a small number; for, in the first, they can involve none of the things in which the bodies differ; and, in the second, none of those in which they agree.

Thus, of the cause or *form* of colour now inquired into, *instantiæ solitariæ* are found in crystals, prisms of glass, drops of dew, which occasionally exhibit colour, and yet have nothing in common with the stones, flowers, and metals, which possess colour permanently, except the colour itself. Hence Bacon concludes, that colour is nothing else than a modification of the rays of light, produced, in the first case, by the different degrees of incidence; and, in the second, by the texture or constitution of the surfaces of bodies. He may be considered as very fortunate in fixing on these examples, for it was by means of them that Newton afterwards found out the composition of light.

Of the second kind of *instantiæ solitariæ*, Bacon mentions the white or coloured veins which occur in limestone or marble, and yet hardly differ in substance or in structure from the ground of the stone. He concludes, very justly, from this, that colour has not much to do with the essential properties of body.

II. The *instantiæ migrantes* exhibit some *nature* or property of body, passing from one condition to another, either from less to greater, or from greater to less; arriving nearer perfection in the first case, or verging towards extinction in the second.

Suppose the thing inquired into were the cause of whiteness in bodies; an *instantia migrans* is found in glass, which, when entire, is without colour, but, when pulverized, becomes white. The same is the case with water unbroken, and water dashed into foam. In both cases, the separation into particles produces whiteness. So also the communication of fluidity to metals by the application of heat; and the destruction of that fluidity by the abstraction of heat, are examples of both kinds of the *instantia migrans*. Instances of this kind are very powerful for reducing the cause inquired after into a narrow space, and for removing all the accidental circumstances. It is necessary, however, as Bacon [1] very justly remarks, that we should consider not merely the case when a certain quality is lost, and another produced, but the gradual changes made in those qualities during their migration, viz. the increase of the one, and the corresponding diminution of the other. The quantity which changes proportionally to another, is connected with it either as cause and effect, or as a collateral effect of the same cause. When, again, we find two

---

[1] Nov. Org. Lib. ii. Aph. 23.

qualities which do not increase proportionally, they afford a negative instance, and assure us that the two are not connected simply as cause and effect.

The mineral kingdom is the great theatre of the *instantiæ migrantes*, where the same *nature* is seen in all gradations, from the most perfect state, till it become entirely evanescent. Such are the shells which we see so perfect in figure and structure in limestone, and gradually losing themselves in the finer marbles, till they can no longer be distinguished. The use, also, of one such fact to explain or interpret another, is nowhere so well seen as in the history of the mineral kingdom.

III. In the third place are the *instantiæ ostensivæ*, which Bacon also calls *elucescentiæ* and *predominantes*. They are the facts which show some particular *nature* in its highest state of power and energy, when it is either freed from the impediments which usually counteract it, or is itself of such force as entirely to repress those impediments. For as every body is susceptible of many different conditions, and has many different forms combined in it, one of them often confines, depresses, and hides another entirely, so that it is not easily distinguished. There are found, however, some subjects in which the *nature* inquired into is completely displayed, either by the absence of impediments, or by the predominance of its own power.

Bacon instances the thermometer, or *vitrum calendare*, as exhibiting the expansive power of heat, in a manner more distinct and measurable than in common cases. To this example, which is well chosen, the present state of science enables us to add many others.

If the weight of the air were inquired into, the Torricellian experiment or the barometer affords an *ostensive instance*, where the circumstance which conceals the weight of the atmosphere in common cases, namely, the pressure of it in all directions, being entirely removed, that weight produces its full effect, and sustains the whole column of mercury in the tube. The barometer affords also an example of the *instantia migrans*, when the change is not total, but only partial, or progressive. If it be the weight of the air which supports the mercury in the tube of the barometer, when that weight is diminished, the mercury ought to stand lower. On going to the top of a mountain, the weight of the incumbent air is diminished, because a shorter column of air is to be sustained; the mercury in the barometer ought therefore to sink, and it is found to do so accordingly.

These are instances in which the action of certain principles is rendered visible by the removal of all the opposing forces. One may be given where it is the distinct and decisive nature of the fact which leads to the result.

Suppose it were inquired, whether the present land had ever been covered by the sea.

If we look at the stratified form of so large a portion of the earth's surface, we cannot but conclude it to be very probable that such land was formed at the bottom of the sea. But the decisive proof is afforded by the shells and corals, or bodies having the perfect shape of shells and corals, and of other marine exuviæ, which are found imbedded in masses of the most solid rock, and often on the tops of very high mountains. This leaves no doubt of the formation of the land under the sea, though it does not determine whether the land, since its formation, has been elevated to its present height, or the sea depressed to its present level. The decision of that question requires other facts to be consulted.

IV. The *instantia clandestina*, which is, as it were, opposed to the preceding, and shows some power or quality just as it is beginning to exist, and in its weakest state, is often very useful in the generalization of facts. Bacon also gave to this the fanciful name of *instantia crepusculi.*

An example of this may be given from hydrostatics. If the suspension of water in capillary tubes be inquired into, it becomes very useful to view that effect when it is least, or when the tube ceases to be capillary, and becomes a vessel of a large diameter. The column is then reduced to a slender ring of water which goes all round the vessel, and this, though now so inconsiderable, has the property of being independent of the size of the vessel, so as to be in all cases the same when the materials are the same. As there can be no doubt that this ring proceeds from the attraction of the sides, and of the part immediately above the water, so there can be no doubt that the capillary suspension, in part at least, is derived from the same cause. An effect of the opposite kind takes place when a glass vessel is filled with mercury.

V. Next to these may be placed what are called *instantiæ manipulares*, or collective instances, that is, general facts, or such as comprehend a great number of particular cases. As human knowledge can but seldom reach the most general cause or *form*, such collective instances are often the utmost extent to which our generalization can be carried. They have great value on this account, as they likewise have on account of the assistance which they give to farther generalization.

Of this we have a remarkable instance in one of the most important steps ever taken in any part of human knowledge. The laws of Kepler are facts of the kind now treated of, and consist of three general truths, each belonging to the whole planetary system, and it was by means of them that Newton discovered the principle of gravitation. The first is, that the planets all move in elliptical orbits, having the sun for their common focus; the next, that about this focus the *radius vector* of each planet describes equal

areas in equal times. The third and last, that the squares of the periodic times of the planets are as the cubes of their mean distances from the sun. The knowledge of each of these was the result of much research, and of the comparison of a vast multitude of observations, insomuch that it may be doubted if ever three truths in science were discovered at the expence of so much labour and patience, or with the exertion of more ingenuity and invention in imagining and combining observations. These discoveries were all made before Bacon wrote, but he is silent concerning them; for the want of mathematical knowledge concealed from his view some of the most splendid and interesting parts of science.

Astronomy is full of such collective instances, and affords them, indeed, of the second and third order, that is to say, two or three times generalized. The astronomer observes nothing but that a certain luminous disk, or perhaps merely a luminous point, is in a certain position, in respect of the planes of the meridian and the horizon, at a certain moment of time. By comparing a number of such observations, he finds that this luminous point moves in a certain plane, with a certain velocity, and performs a revolution in a certain time. Thus, the periodic time of a planet is itself a collective fact, or a single fact expressing the result of many hundred observations. This holds with respect to each planet, and with respect to each element, as it is called, of the planet's orbit, every one of which is a general fact, expressing the result of an indefinite number of particulars. This holds still more remarkably of the inferences which extend to the distances of the planet from the earth, or from the sun. The laws of Kepler are therefore collective facts of the second, or even a higher order; or such as comprehend a great number of general facts, each of which is itself a general fact, including many particulars. It is much to the credit of astronomy, that, in all this process, no degree of truth or certainty is sacrificed; and that the same demonstrative evidence is preserved from the lowest to the highest point. Nothing but the use of mathematical reasoning could secure this advantage to any of the sciences.

VI. In the next place may be ranked the instances which Bacon calls *analogous*, or *parallel*. These consist of facts, between which an analogy or resemblance is visible in some particulars, notwithstanding great diversity in all the rest. Such are the telescope and microscope, in the works of art, compared with the eye in the works of nature. This, indeed, is an analogy which goes much beyond the mere exterior; it extends to the internal structure, and to the principle of action, which is the same in the eye and in the telescope,—to the *latent schematism*, in the language of Bacon, as far as material substance is concerned. It was the experiment of the *camera obscura* which led to the

discovery of the formation of the images of external objects in the bottom of the eye by the action of the crystalline lens, and the other humours of which the eye is formed.

Among the instances of conformity, those are the most useful which enable us to compare productions of an unknown formation, with similar productions of which the formation is well understood. Such are basalt, and the other trap rocks, compared with the lava thrown out from volcanoes. They have a structure so exactly similar, that it is hardly possible to doubt that their origin is the same, and that they are both produced by the action of subterraneous fire. There are, however, amid their similarity, some very remarkable differences in the substances which they contain, the trap rocks containing calcareous spar, and the lava never containing any. On the supposition that they are both of igneous origin, is there any circumstance, in the conditions in which heat may have been applied to them, which can account for this difference? Sir James Hall, in a train of most philosophical and happily contrived experiments, has explained the nature of those conditions, and has shown that the presence of calcareous spar, or the want of it, may arise from the greater or less compression under which the fusion of the basalt was performed. This has served to explain a great difficulty in the history of the mineral kingdom.

Comparative anatomy is full of analogies of this kind, which are most instructive, and useful guides to discovery. It was by remarking in the blood-vessels a contrivance similar to the valves used in hydraulic engines, for preventing the counter current of a fluid, that Harvey was led to the discovery of the circulation of the blood. The analogies between natural and artificial productions are always highly deserving of notice.

The facts of this class, however, unless the analogy be very close, are apt to mislead, by representing accidental regularity as if it were constant. Of this we have an example in the supposed analogy between the colours in the prismatic spectrum and the divisions of the monochord. The colours in the prismatic spectrum do not occupy the same proportion of it in all cases: the analogy depends on the particular kind of glass, not on any thing that is common to all refraction. The tendency of man to find more order in things than there actually exists, is here to be cautiously watched over.

VII. *Monodic*, or singular facts, are the next in order. They comprehend the instances which are particularly distinguished from all those of the genus or species to which they belong. Such is the sun among the stars, the magnet among stones, mercury among metals, boiling fountains among springs, the elephant among quadrupeds. So also among the planets, Saturn is singular from his ring, the new planets are so likewise from their small size, from being extrazodiacal, &c.

Connected with these are the irregular and deviating instances, in which nature seems to depart from her ordinary course. Earthquakes, extraordinary tempests, years of great scarcity, winters of singular severity, &c. are of this number. All such facts ought to be carefully collected; and there should be added an account of all monstrous productions, and of every thing remarkable for its novelty and its rareness. Here, however, the most severe criticism must be applied; every thing connected with superstition is suspicious, as well as whatever relates to alchemy or magic.

A set of facts, which belongs to this class, consists of the instances in which *stones* have so often of late years been observed to fall from the heavens. Those stones are so unlike other atmospherical productions, and their origin must be so different from that of other minerals, that it is scarcely possible to imagine any thing more anomalous, and more inconsistent with the ordinary course of our experience. Yet the existence of this phenomenon is so well authenticated by testimony, and by the evidence arising from certain physical considerations, that no doubt with respect to it can be entertained, and it must therefore be received, as making a part of the natural history of meteors. But as every fact, or class of facts, which is perfectly singular, must be incapable of explanation, and can only be understood when its resemblance to other things has been discovered, so at present we are unable to assign the cause of these phenomena, and have no right to offer any theory of their origin.

VIII. Another class of facts is composed of what Bacon calls *instantiæ comitatus*, or examples of certain qualities which always accompany one another. Such are flame and heat,—flame being always accompanied by heat, and the same degree of heat in a given substance being always accompanied with flame. So also heat and expansion,—an increase of heat being accompanied with an increase of volume, except in a very few cases, and in circumstances very particular.

The most perfect *instantia comitatus* known, as being without any negative, is that of body and weight. Whatever is impenetrable and inert, is also heavy in a degree proportional to its inertia. To this there is no exception, though we do not perceive the connection as necessary.

Hostile instances, or those of perpetual separation, are the reverse of the former.

Examples of this are found in air, and the other elastic fluids, which cannot have a solid form induced on them by any known means, when not combined with other substances. So also in solids, transparency and malleability are never joined, and appear to be incompatible, though it is not obvious for what reason.

IX. Passing over several classes which seem of inferior importance, we come to the *in-*

stantia crucis, the division of this experimental logic which is most frequently resorted to in the practice of inductive investigation. When, in such an investigation, the understanding is placed in *equilibrio*, as it were, between two or more causes, each of which accounts equally well for the appearances, as far as they are known, nothing remains to be done but to look out for a fact which can be explained by the one of these causes, and not by the other; if such a one can be found, the uncertainty is removed, and the true cause is determined. Such facts perform the office of a cross, erected at the separation of two roads, to direct the traveller which he is to take, and, on this account, Bacon gave them the name of *instantiæ crucis*.

Suppose that the subject inquired into were the motion of the planets, and that the phenomena which first present themselves, or the motion of these bodies in longitude, could be explained equally on the Ptolemaic and the Copernican system, that is, either on the system which makes the Earth, or that which makes the Sun, the centre of the planetary motions, a cautious philosopher would hesitate about which of the two he should adopt, and notwithstanding that one of them was recommended by its superior simplicity, he might not think himself authorized to give to it a decided preference above the other. If, however, he consider the motion of these bodies in latitude, that is to say, their digressions from the plane of the ecliptic, he will find a set of phenomena which cannot be reconciled with the supposition that the earth is the centre of the planetary motions, but which receive the most simple and satisfactory explanation from supposing that the sun is at rest, and is the centre of those motions. The latter phenomena would therefore serve as *instantiæ crucis*, by which the superior credibility of the Copernican system was fully evinced.

Another example which I shall give of an *instantia crucis* is taken from chemistry, and is, indeed, one of the most remarkable experiments which has been made in that science.

It is a general fact observed in chemistry, that metals are always rendered heavier by calcination. When a mass of tin or lead, for instance, is calcined in the fire, though every precaution is taken to prevent any addition from the adhesion of ashes, coals, &c. the absolute weight of the mass is always found to be increased. It was long before the cause of this phenomenon was understood. There might be some heavy substance added, though what it was could not easily be imagined; or some substance might have escaped, which was in its nature light, and possessed a tendency upwards. Other phenomena, into the nature of which it is at present unnecessary to inquire, induced chemists to suppose, that in calcination a certain substance actually escapes, being present in the regulus, but not in

the calx of the metal. This substance, to which they gave the name of phlogiston, was probably that which, by its escape, rendered the metal heavier, and must, therefore, be itself endued with absolute levity.

The *instantia crucis* which extricated philosophers from this difficulty, was furnished by an experiment of the celebrated Lavoisier. That excellent chemist included a quantity of tin in a glass retort, hermetically sealed, and accurately weighed together with its contents; he then applied the necessary heat, and when the calcination of the tin was finished, he found the weight of the whole precisely the same as before. This proved, that no substance, which was either light or heavy, in a sensible degree, had made its way through the glass. The experiment went still farther. When the retort was cooled and opened, the air rushed in, so that it was evident that a part of the air had disappeared, or had lost its elasticity. On weighing the whole apparatus, it was now found that its weight was increased by ten grains; so that ten grains of air had entered into the retort when it was opened. The calx was next taken out, and weighed separately, and it was found to have become heavier by ten grains precisely. The ten grains of air then which had disappeared, and which had made way for the ten grains that rushed into the retort, had combined with the metal during the process of calcination. The farther prosecution of this very decisive experiment led to the knowledge of that species of air which combines with metals when they are calcined. The doctrine of phlogiston was of course exploded, and a creature of the imagination replaced by a real existence.

The principle which conducts to the contrivance of an *experimentum crucis* is not difficult to be understood. Taking either of the hypotheses, its consequences must be attempted to be traced, supposing a different experiment to be made. This must be done with respect to the other hypothesis, and a case will probably at last occur, where the two hypotheses would give different results. The experiment made in those circumstances will furnish an *instantia crucis*.

Thus, if the experiment of calcination be performed in a close vessel, and if phlogiston be the cause of the increase of weight, it must either escape through the vessel, or it must remain in the vessel after separation from the calx. If the former be the case, the apparatus will be increased in weight; if the latter, the phlogiston must make its escape on opening the vessel. If neither of these be the case, it is plain that the theory of phlogiston is insufficient to explain the facts.

The *experimentum crucis* is of such weight in matters of induction, that in all those branches of science where it cannot easily be resorted to (the circumstances of an experiment being out of our power, and incapable of being varied at pleasure), there is often a

great want of conclusive evidence. This holds of agriculture, medicine, political economy, &c. To make one experiment, similar to another in all respects but one, is what the *experimentum crucis*, and, in general, the process of induction, principally requires; but it is what, in the sciences just named, can seldom be accomplished. Hence the great difficulty of separating the causes, and allotting to each its due proportion of the effect. Men deceive themselves in consequence of this continually, and think they are reasoning from fact and experience, when, in reality, they are only reasoning from a mixture of truth and falsehood. The only end answered by facts so incorrectly apprehended, is that of making error more incorrigible.

Of the twenty-seven classes into which *instantiæ* are arranged by the author of the *Novum Organum*, fifteen immediately address themselves to the Understanding; five serve to correct or to inform the Senses; and seven to direct the hand in raising the superstructure of Art on the foundation of Science. The examples given above are from the first of these divisions, and will suffice for a summary. To the five that follow next, the general name of *instantiæ lampadis* is given, from their office of assisting or informing the senses.

Of these the *instantiæ januæ* assist the immediate action of the senses, and especially of sight. The examples quoted by Bacon are the microscope and telescope (which last he mentions as the invention of Galileo), and he speaks of them with great admiration, but with some doubt of their reality.

The *instantiæ citantes* enable us to perceive things which are in themselves insensible, or not at all the objects of perception. They cite or place things, as it were, before the bar of the senses, and from this analogy to judicial proceedings is derived the name of *instantiæ citantes*. Such, to employ examples which the progress of science has unfolded since the time of Bacon, are the air-pump and the barometer for manifesting the weight and elasticity of air; the measurement of the velocity of light, by means of the eclipses of the satellites of Jupiter, and the aberration of the fixed stars; the experiments in electricity and Galvanism, and in the greater part of pneumatic chemistry. In all these instances things are made known which before had entirely escaped the senses.

The *instantiæ viæ* are facts which manifest the continuous progress of nature in her operations. There is a propensity in men to view nature as it were at intervals, or at the ends of fixed periods, without regarding her gradual and unceasing action.[1] The desire

---

[1] Nov. Org. II. Aph. 41.

of making observation easy is the great source of this propensity. Men wish for knowledge, but would obtain it at the least expence of time and labour. As there is no time, however, at which the hand of nature ceases to work, there ought to be none at which observation ceases to be made.

The *instantiæ persecantes*, or *vellicantes*, are those which force us to attend to things which, from their subtlety and minuteness, escape common observation.

Some of Bacon's remarks on this subtlety are such as would do credit to the most advanced state of science, and show how much his mind was fitted for distinguishing and observing the great and admirable in the works of nature.

The last division contains seven classes, of which I mention only two. The experiments of this division are those most immediately tending to produce the improvement of art from the extension of science. "Now there are," says Bacon, "two ways in which knowledge, even when sound in itself, may fail of becoming a safe guide to the artist, and these are either when it is not sufficiently precise, or when it leads to more complicated means of producing an effect than can be employed in practice. There are therefore two kinds of experiments which are of great value in promoting the alliance between knowledge and power;—those which tend to give accurate and exact measures of objects, and those which disencumber the processes deduced from scientific principles of all unnecessary operations."

In the *instantiæ radii* we measure objects by lines and angles; in the *instantiæ curriculi* by time or by motion.

To the former of these classes are to be referred a number of instruments which now constitute the greater part of the apparatus of natural philosophy. Though Bacon had a just idea of their utility in general, he was unacquainted with most of them. The most remarkable at present are those that follow:

1. Astronomical instruments, or, more generally, all instruments for measuring lines and angles.

2. Instruments for measuring weight or force; such are the common balance, the hydrostatic balance, the barometer, the instruments used in England by Cavendish, and in France by Coulomb, which measure small and almost insensible actions by the force of torsion.

These last rather belong to the class of the *instantiæ luctæ*, where force is applied as the measure of force, than to the *instantiæ radii*.

3. The thermometer, newly invented in the time of Bacon, and mentioned by him un-

der the name of *Vitrum Calendare*, an instrument to which we owe nearly all the knowledge we have of one of the most powerful agents in nature, viz. Heat.

4. The hygrometer, an instrument for measuring the quantity of humidity contained in the air; and in the construction of which, after repeated failures by the most skilful experimenters, the invention of Professor Leslie now promises success. Almost every one of these instruments, to which several more might be added, has brought in sight a new country, and has enriched science not only with new facts, but with new principles.

Among the remarks of Bacon on the *experimenta radii*, some are very remarkable for the extent of view which they display even in the infancy of physical science. He mentions the forces by which bodies act on one another at a distance, and throws out some hints at the attraction which the heavenly bodies exert on one another.

"Inquirendum est," says he, "si sit vis aliqua magnetica quæ operetur per consensum inter globum terræ et ponderosa, aut inter globum lunæ et aquas maris, aut inter cœlum stellatum, et planetas per quam avocentur et atollantur ad sua apogæa; hæc omnia operantur ad distantias admodum longinquas."[1]

Under the head of the *instantia curriculi*, or the measuring of things by time; after remarking that every change and every motion requires time, and illustrating this by a variety of instances, he has the following very curious anticipation of facts, which appeared then doubtful, but which subsequent discovery has ascertained:

"The consideration of those things produced in me a doubt altogether astonishing, viz. Whether the face of the serene and starry heavens be seen at the instant it really exists, or not till some time later; and whether there be not, with respect to the heavenly bodies, a true time and an apparent time, no less than a true place, and an apparent place, as astronomers say, on account of parallax. For it seems incredible that the *species* or rays of the celestial bodies can pass through the immense interval between them and us in an instant, or that they do not even require some considerable portion of time."[2]

The measurement of the velocity of light, and the wonderful consequences arising from it, are the best commentaries on this passage, and the highest eulogy on its author.

Such were the speculations of Bacon, and the rules he laid down for the conduct of experimental inquiries, before any such inquiries had yet been instituted. The power and compass of a mind which could form such a plan beforehand, and trace not merely the

[1] Nov. Org. II. Aph. 45. [2] Ibid. Aph. 46.

outline, but many of the most minute ramifications, of sciences which did not yet exist, must be an object of admiration to all succeeding ages. He is destined, if, indeed, any thing in the world be so destined, to remain an *instantia singularis* among men, and as he has had no rival in the times which are past, so is he likely to have none in those which are to come. Before any parallel to him can be found, not only must a man of the same talents be produced, but he must be placed in the same circumstances; the memory of his predecessor must be effaced, and the light of science, after being entirely extinguished, must be again beginning to revive. If a second Bacon is ever to arise, he must be ignorant of the first.

Bacon is often compared with two great men who lived nearly about the same time with himself, and who were both eminent reformers of philosophy, Descartes and Galileo.

Descartes flourished about forty years later than Bacon, but does not seem to have been acquainted with his writings. Like him, however, he was forcibly struck with the defects of the ancient philosophy, and the total inaptitude of the methods which it followed, for all the purposes of physical investigation. Like him, too, he felt himself strongly impelled to undertake the reformation of this erroneous system; but the resemblance between them goes no farther; for it is impossible that two men could pursue the same end by methods more diametrically opposite.

Descartes never proposed to himself any thing which had the least resemblance to induction. He began with establishing principles, and from the existence of the Deity and his perfections, he proposed to deduce the explanation of all the phenomena of the world, by reasoning *a priori*. Instead of proceeding upward from the effect to the cause, he proceeded continually downward from the cause to the effect. It was in this manner that he sought to determine the laws of motion, and of the collision of bodies, in which last all his conclusions were erroneous. From the same source he deduced the existence of a *plenum*, and the continual preservation of the same quantity of motion in the universe; a proposition which, in a certain sense, is true, but in the sense in which he understood it, is altogether false. Reasonings of the kind which he employed may possibly suit, as Bacon observed, with intelligences of a higher order than man, but to his case they are quite inapplicable. Of the fruit of this tree nature has forbidden him to eat, and has ordained, that, with the sweat of his brow, and the labour of his hands, he should earn his knowledge as well as his subsistence.

Descartes, however, did not reject experiment altogether, though he assigned it a very subordinate place in his philosophy. By reasoning down from first principles, he tells us that he was always able to discover the effects; but the number of different shapes which

those effects might assume was so great, that he could not determine, without having recourse to experiment, which of them nature had preferred to the rest. " We employ experiment," says he, " not as a reason by which any thing is proved, for we wish to deduce effects from their causes, and not conversely causes from their effects. We appeal to experience only, that out of innumerable effects which may be produced from the same cause, we may direct our attention to one rather than another." It is wonderful, that Descartes did not see what a severe censure he was here passing on himself; of how little value the speculations must be that led to conclusions so vague and indefinite; and how much more philosophy is disgraced by affording an explanation of things which *are not*, than by *not* affording an explanation of things which *are*.

As a system of philosophy and philosophic investigation, the method of Descartes can, therefore, stand in no comparison with that of Bacon. Yet his physics contributed to the advancement of science, but did so, much more by that which they demolished, than by that which they built up. In some particular branches the French philosopher far excelled the English. He greatly improved the science of optics, and in the pure mathematics, as has been already shown, he left behind him many marks of a great and original genius. He will, therefore, be always numbered among those who have essentially contributed to the advancement of knowledge, though nothing could be more perverse than his method of philosophizing, and nothing more likely to impede the progress of science, had not an impulse been at that time given to the human mind which nothing could resist.

Galileo, the other rival and contemporary of Bacon, is, in truth, one of those to whom human knowledge is under the greatest obligations. His discoveries in the theory of motion, in the laws of the descent of heavy bodies, and in the motion of projectiles, laid the foundation of all the great improvements which have since been made by the application of mathematics to natural philosophy. If to this we add the invention of the telescope, the discoveries made by that instrument, the confirmations of the Copernican system which these discoveries afforded, and, lastly, the wit and argument with which he combated and exposed the prejudice and presumption of the schools, we must admit that the history of human knowledge contains few greater names than that of Galileo. On comparing him with Bacon, however, I have no hesitation in saying, that the latter has given indications of a genius of a still higher order. In this I know that I differ from a historian, who was himself a philosopher, and whose suffrage, of consequence, is here of more than ordinary weight.

" The great glory of literature," says Hume, " in this island, during the reign of

James, was Lord Bacon. If we consider the variety of talents displayed by this man, as a public speaker, a man of business, a wit, a courtier, a companion, an author, a philosopher, he is justly entitled to great admiration. If we consider him merely as an author and a philosopher, the light in which we view him at present, though very estimable, he was yet inferior to his contemporary Galileo, perhaps even to Kepler. Bacon pointed out, at a distance, the road to philosophy; Galileo both pointed it out to others, and made himself considerable advances in it. The Englishman was ignorant of geometry; the Florentine revived that science, excelled in it, and was the first who applied it, together with experiment, to natural philosophy. The former rejected, with the most positive disdain, the system of Copernicus; the latter fortified it with new proofs, derived both from reason and the senses. Bacon's style is stiff and rigid; his wit, though often brilliant, is also often unnatural and far-fetched. Galileo is a lively and agreeable, though somewhat a prolix writer."[1]

Though it cannot be denied that there is considerable truth in these remarks, yet it seems to me that the comparison is not made with the justness and discrimination which might have been expected from Hume, who appears studiously to have contrasted what is most excellent in Galileo, with what is most defective in Bacon. It is true that Galileo showed the way in the application of mathematics and of geometry to physical investigation, and that the immediate utility of his performance was greater than that of Bacon's; as it impressed more movement on the age in which he lived, example being always so much more powerful than precept. Bacon, indeed, wrote for an age more enlightened than his own, and it was long before the full merit of his work was understood. But though Galileo was a geometer, and Bacon unacquainted with the mathematics,—though Galileo added new proofs to the system of the earth's motion, which Bacon rejected altogether,—yet is it certain, I think, that the former has more fellows or equals in the world of science than the latter, and that his excellence, though so high, is less unrivalled. The range which Bacon's speculations embraced was altogether immense. He cast a penetrating eye on the whole of science, from its feeblest and most infantine state, to that strength and perfection from which it was then so remote, and which it is perhaps destined to approach to continually, but never to attain. More substitutes might be found for Galileo than for Bacon. More than one could be mentioned, who, in the place of the former, would probably have done what he did; but the history of human knowledge points out nobody of whom it can be said, that, placed in the situation of Bacon, he would have

---

[1] Hist. of England, Vol. VI. Appendix.

done what Bacon did;—no man whose prophetic genius would have enabled him to delineate a system of science which had not yet begun to exist!—who could have derived the knowledge of what *ought to be* from what *was not*, and who could have become so rich in wisdom, though he received from his predecessors no inheritance but their errors. I am inclined, therefore, to agree with D'Alembert, "that when one considers the sound and enlarged views of this great man, the multitude of the objects to which his mind was turned, and the boldness of his style, which unites the most sublime images with the most rigorous precision, one is disposed to regard him as the greatest, the most universal, and the most eloquent of philosophers."[1]

3. Remarks, &c.

It will hardly be doubted by any one who attentively considers the method explained in the *Novum Organum*, which we have now attempted to sketch, that it contains a most comprehensive and rigorous plan of inductive investigation. A question, however, may occur, how far has this method been really carried into practice by those who have made the great discoveries in natural philosophy, and who have raised physical science to its present height in the scale of human knowledge? Is the whole method necessary, or have not circumstances occurred, which have rendered experimental investigation easier in practice than it appears to be in theory? To answer these questions completely, would require more discussion than is consistent with the limits of this Dissertation; I shall, therefore, attempt no more than to point out the principles on which such an answer may be founded.

In a very extensive department of physical science, it cannot be doubted that investigation has been carried on, not perhaps more easily, but with a less frequent appeal to experience, than the rules of the *Novum Organum* would seem to require. In all the physical inquiries where mathematical reasoning has been employed, after a few principles have been established by experience, a vast multitude of truths, equally certain with the principles themselves, have been deduced from them by the mere application of geometry and algebra.

In mechanics, for example, after the laws of motion were discovered, which was done by experiment, the rest of the science, to a great extent, was carried on by reasoning from those laws, in the same manner that the geometer makes his discoveries by reasoning on

---

[1] Discours Préliminaire de l'Encyclopédie.

the definitions, by help of a few axioms, or self-evident propositions. The only difference is, that, in the one case, the definitions and axioms are supplied solely from the mind itself, while, in the other, all the definitions and axioms, which are not those of pure geometry, are furnished by experience.[1]

Bacon certainly was not fully aware of the advantages that were thus to accrue to the physical sciences. He was not ignorant, that the introduction of mathematical reasoning into those sciences is not only possible, but that, under certain conditions, it may be attended with the greatest advantage. He knew also in what manner this application had been abused by the Platonists, who had attempted, by means of geometry, to establish the first principles of physics, or had used them, *in axiomatis constituendis*, which is exactly the province belonging exclusively to experience. At the same time, he pointed out, with great precision, the place which the mathematics may legitimately occupy, as serving to measure and compare the objects of physical inquiry. He did not, however, perceive beforehand, nor was it possible that he should, the vast extent to which the application of that science was capable of being carried. In the book, *De Augmentis*, he has made many excellent remarks on this subject, full of the sagacity which penetrated so far into futurity, but, nevertheless, could only perceive a small part of the scene which the genius of Newton was afterwards to unfold.

Hence, the route which leads to many of the richest and most fertile fields of science, is not precisely that which Bacon pointed out; it is safer and easier, so that the voyager finds he can trust to his chart and compass alone, without constantly looking out, or having the sounding-line perpetually in his hand.

Another remark I must make on Bacon's method is, that it does not give sufficient importance to the *instantiæ radii*, or those which furnish us with accurate measures of physical quantities. The experiments of this class are introduced as only subservient to practice; they are, however, of infinite value in the theoretical part of induction, or for ascertaining the causes and essences of the things inquired into. We have an instance of this in the discovery of that important truth in physical astronomy, that the moon is retained in her orbit by the force of gravity, or the same which, at the earth's surface, makes a stone fall to the ground. This proposition, however it might have been suspected to be true, could never have been demonstrated but by such observations and experiments

[1] The part of mechanics which involves only statical considerations, or the equilibrium of forces, is capable of being treated by *reasoning a priori* entirely, without any appeal to experience. This will appear, when the subject of Mechanics is more particularly treated of.

as assigned accurate geometrical measures to the quantities compared. The semidiameter of the earth; the velocity of falling bodies at the earth's surface; the distance of the moon, and her velocity in her orbit;—all these four elements must be determined with great precision, and afterwards compared together by certain theorems deduced from the laws of motion, before the relation between the force which retains the moon in her orbit, and that which draws a stone to the ground, could possibly be discovered. The discovery also, when made, carried with it the evidence of demonstration, so that here, as in many other cases, the *instantiæ radii* are of the utmost importance in the theoretical part of physics.

Another thing to be observed is, that, in many cases, the result of a number of particular facts, or the collective instance arising from them, can only be found out by geometry, which, therefore, becomes a necessary instrument in completing the work of induction. An example, which the science of optics furnishes, will make this clearer than any general description. When light passes from one transparent medium to another it is refracted, that is, it ceases to go on in a straight line, and the angle which the incident ray makes with the superficies which bounds the two *media*, determines that which the refracted ray makes with the same superficies. Now, if we would learn any thing about the relation which these angles bear to one another, we must have recourse to experiment, and all that experiment can do is, for any particular angle of incidence, to determine the corresponding angle of refraction. This may be done in innumerable cases; but, with respect to the general rule which, in every possible case, determines the one of those angles from the other, or expresses the constant and invariable relation which subsists between them,—with respect to it, experiment gives no direct information. The methods of geometry must therefore be called in to our assistance, which, when a constant though unknown relation subsists between two angles, or two variable quantities of any kind, and when an indefinite number of values of those quantities are given, furnishes infallible means of discovering that unknown relation, either accurately, or at least by approximation. In this way it has been found, that, when the two *media* remain the same, the cosines of the angles above mentioned have a constant ratio to one another. Thus it appears, that, after experiment has done its utmost, geometry must be applied before the business of induction can be completed. This can only happen when the experiments afford accurate measures of the quantities concerned, like the *instantiæ radii, curriculi*, &c. and this advantage of admitting generalization with so much certainty is one of their properties, of which it does not appear that even Bacon himself was aware.

Again, from the intimate connection which prevails among the principles of science, the

success of one investigation must often contribute to the success of another, in such a degree as to make it unnecessary to employ the complete apparatus of induction from the beginning. When certain leading principles have been once established, they serve, in new investigations, to narrow the limits within which the thing sought for is contained, and enable the inquirer to arrive more speedily at the truth.

Thus, suppose that, after the nature of the reflection and refraction of light, and particularly of the colours produced by the latter, had been discovered by experiment, the cause of the rainbow were to be inquired into. It would, after a little consideration, appear probable, that the phenomenon to be explained depends on the reflection and refraction of light by the rain falling from a cloud opposite to the sun. Now, since the nature of reflection and refraction are supposed known, we have the principles previously ascertained which are likely to assist in the explanation of the rainbow. We have no occasion, therefore, to enter on the inquiry, as if the powers to be investigated were wholly unknown. It is the combination of them only which is unknown, and our business is to seek so to combine them, that the result may correspond with the appearances. This last is precisely what Newton accomplished, when, by deducing from the known laws of refraction and reflection the breadth of the coloured arch, the diameter of the circle of which it is a part, and the relation of the latter to the place of the spectator and of the sun, he found all these to come out from his calculus, just as they are observed in nature. Thus he proved the truth of his solution by the most clear and irresistible evidence.

The strict method of Bacon is therefore only necessary where the thing to be explained is new, and where we have no knowledge, or next to none, of the powers employed. This is but rarely the case, at least in some of the branches of Physics; and, therefore, it occurs most commonly in actual investigation, that the inquirer finds himself limited, almost from the first outset, to two or three hypotheses, all other suppositions involving inconsistencies which cannot for a moment be admitted. His business, therefore, is to compare the results of these hypotheses, and to consider what consequences may in any case arise from the one that would not arise from the other. If any such difference can be found, and if the matter is a subject of experiment, we have then an *instantia crucis* which must decide the question.

Thus, the *instantia crucis* comes in real practice to be the experiment most frequently appealed to, and that from which the most valuable information is derived.

In executing the method here referred to, the application of much reasoning, and frequently of much mathematical reasoning, is necessary, before any appeal to the experiment can be made, in order to deduce from each of the hypotheses an exact estimate of the con-

sequences to which it leads. Suppose, for instance, that the law by which the magnetic virtue decreases in its intensity, as we recede from its poles, were to be inquired into. It is obvious that the number of hypotheses is here indefinite; and that we have hardly any choice but to begin with the simplest, or with that which is most analogous to the law of other forces propagated from a centre. Whatever law we assume, we must enter into a good deal of geometric reasoning, before a conclusion can be obtained, capable of being brought to the test of experience. The force itself, like all other forces, is not directly perceived, and its effects are not the result of its mere intensity, but of that intensity combined with the figure and magnitude of the body on which its acts; and, therefore, the calculus must be employed to express the measure of the effect, in terms of the intensity and the distance only. This being done, the hypothesis which gives results most nearly corresponding to the facts observed, when the magnet acts on the same body, at different distances, must be taken as the nearest approximation to the truth. We have here an instance of the use of hypothesis in inductive investigation, and, indeed, of the only legitimate use to which it can ever be applied.

It also appears that Bacon placed the ultimate object of philosophy too high, and too much out of the reach of man, even when his exertions are most skilfully conducted. He seems to have thought, that, by giving a proper direction to our researches, and carrying them on according to the inductive method, we should arrive at the knowledge of the essences of the powers and qualities residing in bodies; that we should, for instance, become acquainted with the essence of heat, of cold, of colour, of transparency. The fact, however, is, that, in as far as science has yet advanced, no one essence has been discovered, either as to matter in general, or as to any of its more extensive modifications. We are yet in doubt, whether heat is a peculiar motion of the minute parts of bodies, as Bacon himself conceived it to be; or something emitted or radiated from their surfaces; or lastly, the vibrations of an elastic medium, by which they are penetrated and surrounded. Yet whatever be the form or essence of heat, we have discovered a great number of its properties and its laws; and have done so, by pursuing with more or less accuracy the method of induction. We have also this consolation for the imperfection of our theoretical knowledge, that, in as much as art is concerned, or the possession of power over heat, we have perhaps all the advantages that could be obtained from a complete knowledge of its essence.

An equal degree of mystery hangs over the other properties and modifications of body; light, electricity, magnetism, elasticity, gravity, are all in the same circumstances; and the only advance that philosophy has made toward the discovery of the essences of these qua-

lities or substances is, by exploding some theories, rather than by establishing any,—so true is Baccn's maxim, that the first steps in philosophy necessarily consist in negative propositions. Besides this, in all the above instances the laws of action have been ascertained; the phenomena have been reduced to a few general facts, and in some cases, as in that of gravity, to one only; and for ought that yet appears, this is the highest point which our science is destined to reach.

In consequence of supposing a greater perfection in knowledge than is ever likely to be attained, Bacon appears, in some respects, to have misapprehended the way in which it is ultimately to become applicable to art. He conceives that, if the *form* of any quality were known, we should be able, by inducing that form on any body, to communicate to it the said quality. It is not probable, however, that this would often lead to a more easy and simple process than that which art has already invented. In the case of colour, for example, though ignorant of its *form*, or of the construction of surface which enables bodies to reflect only light of a particular species, yet we know how to communicate that power from one body to another. Nor is it likely, though this structure were known with ever so great precision, that we should be able to impart it to bodies by any means so simple and easy, as by the common process of immersing them in a liquid of a given colour.

In some instances, however, the theories of chemistry have led to improvements of art very conformable to the anticipations of the *Novum Organum*. A remarkable instance of this occurs in the process for bleaching, invented by Berthollet. It had been for some time known, that the combination of the chemical principle of oxygen with the colouring matter in bodies, destroyed, or discharged, the colour; and that, in the common process of bleaching, it was chiefly by the union of the oxygen of the air with the colouring matter in the cloth that this effect was produced. The excellent chemist just named conceived, therefore, that if the oxygen could be presented to the cloth in a dense state, and, at the same time, feebly combined with any other body, it might unite itself to the colouring matter so readily, that the process of bleaching would by that means be greatly accelerated. His skill in chemistry suggested to him a way in which this might easily be done, by immersing the cloth in a liquid containing much oxygen in a loose state, or one in which it was slightly combined with other substances, and the effect followed so exactly, that he was able to perform in a few hours what required weeks, and even months, according to the common process. This improvement, therefore, was a real gift from the sciences to the arts; and came nearly, though not altogether, up to the ideas of Bacon. I suspect

not altogether, because the manner in which oxygen destroys the colour of bodies, or alters the structure of their surfaces, remains quite unknown.

It was natural, however, that Bacon, who studied these subjects theoretically, and saw nowhere any practical result in which he could confide, should listen to the inspirations of his own genius, and ascribe to philosophy a perfection which it may be destined never to attain. He knew, that from what it had not yet done, he could conclude nothing against what it might hereafter accomplish. But after his method has been followed, as it has now been, with greater or less accuracy, for more than two hundred years, circumstances are greatly changed; and the impediments, which, during all that time, have not yielded in the least to any effort, are perhaps never likely to be removed. This may, however, be a rash inference; Bacon, after all, may be in the right; and we may be judging under the influence of the vulgar prejudice, which has convinced men, in every age, that they had nearly reached the farthest verge of human knowledge. This must be left for the decision of posterity; and we should rejoice to think, that judgment will hereafter be given against the opinion which at this moment appears most probable.

Section III.

MECHANICS.

1. Theory of Motion.

Before the end of the sixteenth century, mechanical science had never gone beyond the problems which treat of the equilibrium of bodies, and had been able to resolve these accurately, only in the cases which can be easily reduced to the lever. Guido Ubaldi, an Italian mathematician, was among the first who attempted to go farther than Archimedes and the ancients had done in such inquiries. In a treatise which bears the date of 1577, he reduced the pulley to the lever, but with respect to the inclined plane, he continued in the same error with Pappus Alexandrinus, supposing that a certain force must be applied to sustain a body, even on a plane which has no inclination.

Stevinus, an engineer of the Low Countries, is the first who can be said to have passed beyond the point at which the ancients had stopped, by determining accurately the force necessary to sustain a body on a plane inclined at any angle to the horizon. He resolved

also a great number of other problems connected with the preceding, but, nevertheless, did not discover the general principle of the composition of forces, though he became acquainted with this particular case, immediately applicable to the inclined plane.

The remark, that a chain laid on an inclined plane, with a part of it hanging over at top, in a perpendicular line, will be *in equilibrio*, if the two ends of the chain reach down exactly to the same level, led him to the conclusion, that a body may be supported on such a plane by a force which draws in a direction parallel to it, and has to the weight of the body the same ratio that the height of the plane has to its length.

Though it was probably from experience that Stevinus derived the knowledge of this proposition, he attempted to prove the truth of it by reasoning *a priori*. He supposed the two extremities of the chain, when disposed as above, to be connected by a part similar to the rest, which, therefore, must hang down, and form an arch. If in this state, says he, the chain were to move at all, it would continue to move for ever, because its situation, on the whole, never changing, if it were determined to move at one instant, it must be so determined at every other instant. Now, such perpetual motion, he adds, is impossible, and therefore the chain, as here supposed, with the arch hanging below, does not move. But the force of the arch below draws down the ends of the chain equally, because the arch is divided in the middle or lowest point into two parts similar and equal. Take away these two equal forces, and the remaining forces will also be equal, that is, the tendency of the chain to descend along the inclined plane, and the opposite tendency of the part hanging perpendicularly down, are equal, or are *in equilibrio* with one another. Such is the reasoning of Stevinus, which, whether perfectly satisfactory or not, must be acknowledged to be extremely ingenious, and highly deserving of attention, as having furnished the first solution of a problem, by which the progress of mechanical science had been long arrested. The first appearance of his solution is said to have had the date of 1585; but his works, as we now see them, were collected after his death, by his countryman Albert Girard, and published at Leyden in 1634.[1] Some discoveries of Stevinus in hydrostatics will be hereafter mentioned.

The person who comes next in the history of mechanics made a great revolution in the physical sciences. Galileo was born at Pisa in the year 1564. He early applied himself

---

[1] The edition of Albert Girard is entitled *Oeuvres Mathematiques de Stevins*, in folio. See Livre I. *De la Statique*, theorem 11. Stevinus also wrote a treatise on navigation, which was published in Flemish in 1586, and was afterwards honoured with a translation into Latin, by Grotius. The merit of Stevinus has been particularly noticed by La Grange. *Mecanique Analytique*, Tom. I. Sect. 1. § 5.

to the study of mathematics and natural philosophy ; and it is from the period of his discoveries that we are to date the joint application of experimental and geometrical reasoning to explain the phenomena of nature.

As early as 1592 he published a treatise, *della Scienza Mechanica*, in which he has given the theory, not of the lever only, but of the inclined plane and the screw ; and has also laid down this general proposition, that mechanical engines make a small force equivalent to a great one, by making the former move over a greater space in the same time than the latter, just in proportion as it is less. No contrivance can make a small weight put a great one in motion, but such a one as gives to the small weight a velocity which is as much greater than that of the large weight, as this last weight is greater than the first. These general propositions, and their influence on the action of machinery, Galileo proceeded to illustrate with that clearness, simplicity, and extent of view, in which he was quite unrivalled ; and hence, I think, it is fair to consider him as the first person to whom the mechanical principle, since denominated that of *the virtual velocities*, had occurred in its full extent. The object of his consideration was the action of machines in motion, and not merely of machines *in equilibrio*, or at rest ; and he showed, that, if the effect of a force be estimated by the weight it can raise to a given height in a given time, this effect can never be increased by any mechanical contrivance whatsoever.

In the same treatise, he lays it down as a postulate (*supposizione*), that the effect of one heavy body to turn another round a centre of motion, is proportional to the perpendicular drawn from that centre to the vertical passing through the body, or in general to the direction of the force. This proposition he states without a demonstration, and passes by means of it to the oblique lever, and thence to the inclined plane. To speak strictly, however, the demonstrations with respect to both these last are incomplete, the preceding proposition being assumed in them without proof. It is probable that he satisfied himself of the truth of it, on the principle, that the distances of forces from the centre of motion must always be measured by lines making the *same* angles with their directions, and that of such lines the simplest are the perpendiculars. His demonstration is regarded by La Grange as quite satisfactory.[1]

Galileo extended the theory of motion still farther. He had begun, while pursuing his studies at the university of Pisa, to make experiments on the descent of falling bodies, and discovered the fact, that heavy and light bodies fall to the ground from the same

---

[1] Mecanique Analytique, Tom I. Sect. 1. § 6.

height in the same time, or in times so nearly the same, that the difference can only be ascribed to the resistance of the air. From observing the vibrations of the lamps in the cathedral, he also arrived at this very important conclusion in mechanics, that the great and the small vibrations of the same pendulum are performed in the same time, and that this time depends only on the length of the pendulum. The date of these observations goes back as far as the year 1583.

These experiments drew upon him the displeasure of his masters, who considered it as unbecoming of their pupil to seek for truth in the Book of Nature, rather than in the writings of Aristotle, when elucidated by their commentaries, and, from that moment began the persecutions with which the prejudice, the jealousy, and bigotry of his contemporaries continued to harass or afflict this great man throughout his whole life.

That the acceleration of falling bodies is uniform, or, that they receive equal increments of velocity in equal times, he appears first to have assumed as the law which they follow, merely on account of its simplicity. Having once assumed this principle, he showed, by mathematical reasoning, that the spaces descended through must be as the squares of the times, and that the space fallen through in one second is just the half of that which the body would have described in the same time with the velocity last acquired.

The knowledge which he already had of the properties of the inclined plane enabled him very readily to perceive, that a body descending on such a plane must be uniformly accelerated, though more slowly than when it falls directly, and is accelerated by its whole weight. By means of the inclined plane, therefore, he was able to bring the whole theory of falling bodies to the test of experiment, and to prove the truth of his original assumption, the uniformity of their acceleration.

His next step was to determine the path of a heavy body, when obliquely projected. He showed this path to be a parabola; and here, for the first time, occurs the use of a principle which is the same with the composition of motion in its full extent. Galileo, however, gave no name to this principle; he did not enunciate it generally, nor did he give any demonstration of it, though he employed it in his reasonings. The inertia of body was assumed in the same manner; it was, indeed, involved in the uniform acceleration of falling bodies, for these bodies did not lose in one minute the motion acquired in the preceding, but, retaining it, went on continually receiving more.

The theory of the inclined plane had led to the knowledge of this proposition, that, if a circle be placed vertically, the chords of different arches terminating in the lowest point of the circle, are all descended through in the same space of time. This seemed to explain why, in a circle, the great and the small vibrations are of equal duration. Here,

however, Galileo was under a mistake, as the motions in the chord and in the arch are very dissimilar. The accelerating force in the chord remains the same from the beginning to the end, but, in the arch, it varies continually, and becomes, at the lowest point, equal to nothing. The times in the chords, and in the arches, are therefore different, so that here we have a point marking the greatest distance in this quarter, to which the mechanical discoveries of Galileo extended. The first person who investigated the exact time of a vibration in an arch of a circle was Huygens, a very profound mathematician.

To this list of mechanical discoveries, already so important and extensive, we must add, that Galileo was the first who maintained the existence of the *law of continuity*, and who made use of it as a principle in his reasonings on the phenomena of motion.[1]

The vibrations of the pendulum having suggested to Galileo the means of measuring time accurately, it appears certain that the idea of applying it to the clock had also occurred to him, and of using the chronometer so formed for finding the longitude, by means of observations made on the eclipses of the satellites of Jupiter. How far he had actually proceeded in an invention which required great practical knowledge, and which afterwards did so much credit to Huygens, appears to be uncertain, and not now easy to be ascertained. But that the project had occurred to him, and that he had taken some steps towards realizing it, is sufficiently established.

One forms, however, a very imperfect idea of this philosopher, from considering the discoveries and inventions, numerous and splendid as they are, of which he was the undisputed author. It is by following his reasonings, and by pursuing the train of his thoughts in his own elegant, though somewhat diffuse exposition of them, that we become acquainted with the fertility of his genius, with the sagacity, penetration, and comprehensiveness of his mind. The service which he rendered to real knowledge, is to be estimated not only from the truths which he discovered, but from the errors which he detected,—not merely from the sound principles which he established, but from the pernicious idols which he overthrew. His acuteness was strongly displayed in the address with which he exposed the errors of his adversaries, and refuted their opinions, by comparing one part of them with another, and proving their extreme inconsistency. Of all the writers who have lived in an age, which was yet only emerging from ignorance and barbarism, Galileo has most entirely the tone of true philosophy, and is most free from any contamination of the times in taste, sentiment, and opinion.

---

[1] Opere de Galileo, Tom. IV. Dial. 1. p. 32, Florence edition, and in many other parts.

The discoveries of this great man concerning motion drew the attention of philosophers more readily, from the circumstance that the astronomical theories of Copernicus had directed their attention to the same subject. It had become evident, that the great point in dispute between his system and the Ptolemaic must be finally decided by an appeal to the nature of motion and its laws. The great argument to which the friends of the latter system naturally had recourse was the impossibility, as it seemed to them to be, of the swift motion of the earth being able to exist, without the perception, nay, even without the destruction, of its inhabitants. It was natural for the followers of Copernicus to reply, that it was not certain that these two things were incompatible; that there were many cases in which it appeared, that the motion common to a whole system of bodies did not affect the motion of those bodies relatively to one another; that the question must be more deeply inquired into; and that, without this, the evidence on opposite sides could not be fairly and accurately compared. Thus it was, at a very fortunate moment, that Galileo made his discoveries in Mechanics, as they were rendered more interesting by those which, at that very time, he himself was making in Astronomy. The system of Copernicus had, in this manner, an influence on the theory of motion, and, of course, on all the parts of natural philosophy. The *inertia* of matter, or, the tendency of body, when put in motion, to preserve the quantity and direction of that motion, after the cause which impressed it has ceased to act, is a principle which might still have been unknown, if it had not been forced upon us by the discovery of the motion of the earth.

The first addition which was made to the mechanical discoveries of Galileo was by Torricelli, in a treatise *De Motu Gravium naturaliter descendentium et projectorum.*[1] To this ingenious man we are indebted for the discovery of a remarkable property of the centre of gravity, and a general principle with respect to the equilibrium of bodies. It is this: If there be any number of heavy bodies connected together, and so circumstanced, that by their motion their centre of gravity can neither ascend nor descend, these bodies will remain at rest. This proposition often furnishes the means of resolving very difficult questions in mechanics.

Descartes, whose name is so great in philosophy and mathematics, has also a place in the history of mechanical discovery. With regard to the action of machines, he laid down the same principle which Galileo had established,—that an equal effort is neces-

---

[1] Vitæ Italorum Illustrium, Vol. I. p. 347.

sary to give to a weight a certain velocity, as to give to double the weight the half of that velocity, and so on in proportion, the effect being always measured by the weight multiplied into the velocity which it receives. He could hardly be ignorant that this proposition had been already stated by Galileo, but he has made no mention of it. He, indeed, always affected a disrespect for the reasonings and opinions of the Italian philosopher, which has done him no credit in the eyes of posterity.

The theory of motion, however, has in some points been considerably indebted to Descartes. Though the reasonings of Galileo certainly involve the knowledge of the disposition which matter has to preserve its condition either of rest or of rectilineal and uniform motion, the first distinct enunciation of this law is found in the writings of the French philosopher. It is, however, there represented, not as mere inactivity, or indifference, but as a real force, which bodies exert in order to preserve their state of rest or of motion, and this inaccuracy affects some of the reasonings concerning their action on one another.

Descartes, however, argued very justly, that all motion being naturally rectilineal, when a body moves in a curve, this must arise from some constraint, or some force urging it in a direction different from that of the first impulse, and that if this cause were removed at any time, the motion would become rectilineal, and would be in the direction of a tangent, to the curve at the point where the deflecting force ceased to act.

Lastly, He taught that the quantity of motion in the universe remains always the same.

The reasoning by which he supported the first and second of these propositions is not very convincing, and though he might have appealed to experience for the truth of both, it was not in the spirit of his philosophy to take that method of demonstrating its principles. His argument was, that motion is a state of body, and that body or matter cannot change its own state. This was his demonstration of the first proposition, from which the second followed necessarily.

The evidence produced for the third, or the preservation of the same quantity of motion in the universe, is founded on the immutability of the Divine nature, and is an instance of the intolerable presumption which so often distinguished the reasonings of this philosopher. Though the immutability of the Divine nature will readily be admitted, it remains to be shown, that the continuance of the same quantity of motion in the universe is a consequence of it. This, indeed, cannot be shown, for that quantity, in the sense in which Descartes understood it, is so far from being preserved uniform, that it varies continually from one instant to another. It is nevertheless true, that the

quantity of motion in the universe, when rightly estimated, is invariable, that is, when reduced to the direction of three axes at right angles to one another, and when opposite motions are supposed to have opposite signs. This is a truth now perfectly understood, and is a corollary to the equality of action and reaction, in consequence of which, whatever motion is communicated in one direction, is either lost in that direction, or generated in the opposite. This, however, is quite different from the proposition of Descartes, and if expressed in his language, would assert, not that the sum, but that the difference of the opposite motions in the universe remains constantly the same. When he proceeds, by help of the principle which he had thus mistaken, to determine the laws of the collision of bodies, his conclusions are almost all false, and have, indeed, such a want of consistency and analogy with one another, as ought, in the eyes of a mathematician, to have appeared the most decisive indications of error. How this escaped the penetration of a man well acquainted with the harmony of geometrical truths, and the gradual transitions by which they always pass into one another, is not easily explained, and perhaps, of all his errors, is the least consistent with the powerful and systematic genius which he is so well known to have possessed.

Thus, the obligation which the theory of motion has to this philosopher, consists in his having pointed out the nature of centrifugal force, and ascribed that force to the true cause, the inertia of body, or its tendency to uniform and rectilineal motion.

The laws which actually regulate the collision of bodies remained unknown till some years later, when they were recommended by the Royal Society of London to the particular attention of its members. Three papers soon appeared, in which these laws were all correctly laid down, though no one of the authors had any knowledge of the conclusions obtained by the other two. The first of these was read to the Society, in November 1668, by Dr Wallis of Oxford; the next by Sir Christopher Wren in the month following, and the third by Huygens in January 1669. The equality of action and reaction, and the maxim, that the same force communicates to different bodies velocities which are inversely as their masses, are the principles on which these investigations are founded.

The ingenious and profound mathematician last mentioned is also the first who explained the true relation between the length of a pendulum, and the time of its least vibrations, and gave a rule by which the time of the rectilineal descent, through a line equal in length to the pendulum, might from thence be deduced. He next applied the pendulum to regulate the motion of a clock, and gave an account of his construction, and the principles of it, in his *Horologium Oscillatorium*, about the year 1670, though the date of the inven-

tion goes as far back as 1656.[1] Lastly, He taught how to correct the imperfection of a pendulum, by making it vibrate between cycloidal cheeks, in consequence of which its vibrations, whether great or small, became, not approximately, but precisely of equal duration.

Robert Hooke, a very celebrated English mechanician, laid claim to the same application of the pendulum to the clock, and the same use of the cycloidal cheeks. There is, however, no dispute as to the priority of Huygens' claim, the invention of Hooke being as late as 1670. Of the cycloidal cheeks, he is not likely to have been even the second inventor. Experiment could hardly lead any one to this discovery, and he was not sufficiently skilled in the mathematics to have found it out by mere reasoning. The fact is, that though very original and inventive, Hooke was jealous and illiberal in the extreme; he appropriated to himself the inventions of all the world, and accused all the world of appropriating his.

It has already been observed, that Galileo conceived the application of the pendulum to the clock earlier, by several years, than either of the periods just referred to. The invention did great honour to him and to his two rivals; but that which argues the most profound thinker, and the most skilful mathematician of the three, is the discovery of the relation between the length of the pendulum and the time of its vibration, and this discovery belongs exclusively to Huygens. The method which he followed in his investigation, availing himself of the properties of the cycloid, though it be circuitous, is ingenious, and highly instructive.

An invention, in which Hooke has certainly the priority to any one, is the application of a spiral spring to regulate the balance of a watch. It is well known of what practical utility this invention has been found, and how much it has contributed to the solution of the problem of finding the longitude at sea, to which not only he, but Galileo and Huygens, appear all to have had an eye.

In what respects the theory of motion, Huygens has still another strong claim to our notice. This arises from his solution of the problem of finding the centre of oscillation of a compound pendulum, or the length of the simple pendulum vibrating in the same time with it. Without the solution of this problem, the conclusions respecting the pendulum were inapplicable to the construction of clocks, in which the pendulums used are of necessity compound. The problem was by no means easy, and Huygens was obliged to intro-

---

[1] Montucla, Tom. II. p. 418, 2d edit.

duce a principle which had not before been recognised, that if the compound pendulum, after descending to its lowest point, was to be separated into particles distinct and unconnected with one another, and each left at liberty to continue its own vibration, the common centre of gravity of all those detached weights would ascend to the same height to which it would have ascended had they continued to constitute one body. The above principle led him to the true solution, and his investigation, though less satisfactory than those which have been since given, does great credit to his ingenuity. This was the most difficult mechanical inquiry which preceded the invention of the differential or fluxionary calculus.

2. Hydrostatics.

While the theory of motion, as applied to solids, was thus extended, in what related to fluids, it was making equal progress. The laws which determine the weight of bodies immersed in fluids, and also the position of bodies floating on them, had been discovered by Archimedes, and were farther illustrated by Galileo. It had also been discovered by Stevinus, that the pressure of fluids is in proportion to their depth, and thus the two leading principles of hydrostatics were established. Hydraulics, or the motion of fluids, was a matter of more difficulty, and here the first step is to be ascribed to Torricelli, who, though younger than Galileo, was for some time his contemporary. He proved that water issues from a hole in the side or bottom of a vessel, with the velocity which a body would acquire, by falling from the level of the surface to the level of the orifice. This proposition, now so well known as the basis of the whole doctrine of Hydraulics, was first published by Torricelli at the end of his book, *De Motu Gravium et Projectorum*; but it is not the greatest discovery which science owes to the friend and disciple of Galileo. The latter had failed in assigning the reason why water cannot be raised in pumps higher than thirty-three feet, but he had remarked, that if a pump is more than thirty-three feet in length, a vacuum will be left in it. Torricelli, reflecting on this, conceived, that if a heavier fluid than water were used, a vacuum might be produced, in a way far shorter, and more compendious. He tried mercury, therefore, and made use of a glass tube about three feet long, open at one end, and close at the other, where it terminated in a globe. He filled this tube, shut it with his finger, and inverted it in a basin of mercury. The result is well known;—he found that a column of mercury was suspended in the tube, an effect which he immediately ascribed to the pressure of the atmosphere. So disinterested was this philosopher, however, that he is said to have lamented that Galileo, when inquiring into the cause why water does not ascend in pumps above a certain height, had not discovered

the true cause of the phenomenon. The generosity of Torricelli was perhaps rarer than his genius;—there are more who might have discovered the suspension of mercury in the barometer, than who would have been willing to part with the honour of the discovery to a master or a friend.

This experiment opened the door to a multitude of new discoveries, and demolished a formidable idol, the horror of a vacuum, to which so much power had been long attributed, and before which even Galileo himself had condescended to bow.

The objections which were made to the explanation of the suspension of the mercury in the tube of the barometer, were overthrown by carrying that instrument to the top of Puy de Dome, an experiment suggested by Pascal. The descent of the mercury showed, that the pressure which supported it was less there than at the bottom; and it was afterwards found, that the fall of the mercury corresponded exactly to the diminution of the length of the pressing column, so that it afforded a measure of that diminution, and, consequently, of the heights of mountains. The invention of the air-pump by Otto Guericke, burgomaster of Magdeburg, quickly followed that of the barometer by Torricelli, though it does not appear that the invention of the Italian philosopher was known to the German. In order to obtain a space entirely void of air, Otto Guericke filled a barrel with water, and having closed it exactly on all sides, began to draw out the water by a sucking-pump applied to the lower part of the vessel. He had proceeded but a very little way, when the air burst into the barrel with a loud noise, and its weight was proved by the failure of the experiment, as effectually as it could have been by its success. After some other trials, which also failed, he thought of employing a sphere of glass, when the experiment succeeded, and a vacuum was obtained. This was about the year 1654.

The elasticity of the air, as well as its weight, now became known; its necessity to combustion, and the absorption of a certain proportion of it, during that process; its necessity for conveying sound;—all these things were clearly demonstrated. The necessity of air to the respiration of animals required no proof from experiment, but the sudden extinction of life, by immersion in a vacuum, was a new illustration of the fact.

The first considerable improvements made on the air-pump are due to Mr Boyle. He substituted to the glass globe of Otto Guericke a receiver of a more commodious form, and constructed his pump so as to be worked with much more facility. His experiments were farther extended,—they placed the weight and elasticity of the air in a variety of new lights,—they made known the power of air to dissolve water, &c. Boyle had great skill in contriving, and great dexterity in performing experiments. He had, in-

deed, very early applied himself to the prosecution of experimental science, and was one of the members of the small but distinguished body, who, during the civil wars, held private meetings for cultivating natural knowledge, on the plan of Bacon. They met first in London, as early as 1645, afterwards at Oxford, taking the name of the *Philosophic College*. Of them, when Charles the Second ascended the throne, was formed the Royal Society of London, incorporated by letters patent in 1662. No one was more useful than Boyle in communicating activity and vigour to the new institution. A real lover of knowledge, he was most zealous in the pursuit of it; and having thoroughly imbibed the spirit of Bacon, was an avowed enemy to the philosophy of Aristotle.

Section IV.

ASTRONOMY.

1. Ancient Astronomy.

It has already been remarked, that the ancients made more considerable advances in astronomy than in almost any other of the physical sciences. They applied themselves diligently to observe the heavens, and employed mathematical reasoning to connect together the insulated facts, which are the only objects of direct observation. The astronomer discovers nothing by help of his instruments, but that, at a given instant, a certain luminous point has a particular position in the heavens. The application of mathematics, and particularly of spherical trigonometry, enables him to trace out the precise tract of this luminous spot; to discover the rate of its motion, whether varied or uniform, and thus to resolve the first great problem which the science of astronomy involves, viz. to express the positions of the heavenly bodies, relatively to a given plane in functions of the time. The problem thus generally enunciated, comprehends all that is usually called by the name of descriptive or mathematical astronomy.

The explanation of the celestial motions, which naturally occurred to those who began the study of the heavens, was, that the stars are so many luminous points fixed in the surface of a sphere, having the earth in its centre, and revolving on an axis passing through that centre in the space of twenty-four hours. When it was observed that all the stars did not partake of this diurnal motion in the same degree, but that some were carried slowly towards the east, and that their paths estimated in that direction, after certain in-

tervals of time, returned into themselves, it was believed that they were fixed in the surfaces of spheres, which revolved westward, more slowly than the sphere of the fixed stars. These spheres must be transparent, or made of some crystalline substance, and hence the name of the crystalline spheres, by which they were distinguished. This system, though it grew more complicated in proportion to the number and variety of the phenomena observed, was the system of Aristotle and Eudoxus, and, with a few exceptions, of all the philosophers of antiquity.

But when the business of observation came to be regularly pursued; when Timocharis and Aristillus, and their successors in the Alexandrian school, began to study the phenomena of the heavens, little was said of these orbs; and astronomers seemed only desirous of ascertaining the laws or the general facts concerning the planetary motions.

To do this, however, without the introduction of hypothesis, was certainly difficult, and probably was then impossible. The simplest and most natural hypothesis was, that the planets moved eastward in circles, and at a uniform rate. But when it was found that, instead of moving uniformly to the eastward, every one of them was subject to great irregularity, the motion eastward becoming at certain periods slower, and at length vanishing altogether, so that the planet became stationary, and afterwards acquiring a motion in the contrary direction, proceeded for a time toward the west, it was far from obvious how all these appearances could be reconciled with the idea of a uniform circular motion.

The solution of this difficulty is ascribed to Apollonius Pergæus, one of the greatest geometers of antiquity. He conceived that, in the circumference of a circle, having the earth for its centre, there moved the centre of another circle, in the circumference of which the planet actually revolved. The first of these circles was called the *deferent*, and the second the *epicycle*, and the motion in the circumference of each was supposed uniform. Lastly, it was conceived that the motion of the centre of the epicycle in the circumference of the deferent, and of the planet in that of the epicycle, were in opposite directions, the first being towards the east, and the second towards the west. In this way, the alterations from progressive to retrograde, with the intermediate stationary points, were readily explained, and Apollonius carried his investigation so far as to determine the ratio between the radius of the deferent, and that of epicycle, from knowing the stations and retrogradations of any particular planet.

An object, which was then considered as of great importance to astronomy, was thus accomplished, viz. the production of a variable motion, or one which was continually changing both its rate and its direction from two uniform circular motions, each of which preserved always the same quantity and the same direction.

It was not long before another application was made of the method of epicycles. Hipparchus, the greatest astronomer of antiquity, and one of the inventors in science most justly entitled to admiration, discovered the inequality of the sun's apparent motion round the earth. To explain or to express this irregularity, the same observer imagined an epicycle of a small radius with its centre moving uniformly in the circumference of a large circle, of which the earth was the centre, while the sun revolved in the circumference of the small circle with the same angular velocity as this last, but in a contrary direction.

As other irregularities in the motions of the moon and of the planets were observed, other epicycles were introduced, and Ptolemy, in his *Almagest*, enumerated all which then appeared necessary, and assigned to them such dimensions as enabled them to express the phenomena with accuracy. It is not to be denied that the system of the heavens became in this way extremely complicated; though, when fairly examined, it will appear to be a work of great ingenuity and research. The ancients, indeed, may be regarded as very fortunate in the contrivance of epicycles, because, by means of them, every inequality which can exist in the angular motion of a planet may be at least nearly represented. This I call fortunate, because, at the time when Apollonius introduced the epicycle, he had no idea of the extent to which his contrivance would go, as he could have none of the conclusions which the author of the *Mécanique Céleste* was to deduce from the principle of gravitation.

The same contrivance had another great advantage; it subjected the motions of the sun, the moon, and the planets, very readily to a geometrical construction, or an arithmetical calculation, neither of them difficult. By this means the predictions of astronomical phenomena, the calculation of tables, and the comparison of those tables with observation, became matters of great facility, on which facility, in a great measure, the progress of the science depended. It was on these circumstances, much more than on the simplicity with which it amused or deceived the imagination, that the popularity of this theory was founded; the ascendant which it gained over the minds of astronomers, and the resistance which, in spite of facts and observations, it was so long able to make to the true system of the world.

It does not appear that the ancient astronomers ever considered the epicycles and deferents which they employed in their system as having a physical existence, or as serving to *explain* the causes of the celestial motions. They seem to have considered them merely as mathematical diagrams, serving to *express* or to represent those motions as geometrical expressions of certain general facts, which readily furnished the rules of astronomical calculation.

The language in which Ptolemy speaks of the epicycles is not a little curious, and very conformable to the notion, that he considered them as merely the means of expressing a general law. After laying down the hypothesis of certain epicycles, and their dimensions, it is usual with him to add, " these suppositions will *save* the phenomena." *Save* is the literal translation of the Greek word, which is always a part of the verb Σωζειν, or some of its compounds. Thus, in treating of certain phenomena in the moon's motion, he lays down two hypotheses, by either of which they may be expressed ; and he concludes, " in this way the similitude of the ratios, and the proportionality of the times, will be *saved* (διασώζοιντο) on both suppositions."[1] It is plain, from these words, that the astronomer did not here consider himself as describing any thing which actually existed, but as explaining two artifices, by either of which, certain irregularities in the moon's motion may be represented, in consistence with the principle of uniform velocity. The hypothesis does not relate to the explanation, but merely to the expression of the fact ; it is first assumed, and its merit is then judged of synthetically, by its power to *save*, to reconcile, or to represent appearances. At a time when the mathematical sciences extended little beyond the elements, and when problems which could not be resolved by circles and straight lines, could harldly be resolved at all, such artifices as the preceding were of the greatest value. They were even more valuable than the truth itself would have been in such circumstances ; and nothing is more certain than that the real elliptical orbits of the planets, and the uniform description of areas, would have been very unseasonable discoveries at the period we are now treating of. The hypotheses of epicycles, and of centres of uniform motion,

---

[1] Mathematica Syntaxis, Lib. IV. p. 223 of the Paris edition.——Milton, the extent and accuracy of whose erudition can never be too much admired, had probably in view this phraseology of Ptolemy, when he wrote the following lines :—

——" He his fabric of the Heavens
Hath left to their disputes, perhaps to move
His laughter at their quaint opinions wide
Hereafter, when they come to model Heaven
And calculate the stars, how they will wield
The mighty frame, how build, unbuild, contrive
To *save appearances*, how gird the sphere
With centrick and eccentrick scribbled o'er,
Cycle and epicycle, orb in orb."

The obsolete verb *to salve* is employed by Bacon, and many other of the old English writers in the same sense with Σωζειν in the work of Ptolemy here referred to. " The schoolmen were like the astronomers, who, to *salve* phenomena, framed to their conceit eccentricks and epicycles ; so they, to *salve* the practice of the church, had devised a great number of strange positions." Bacon.

were well accommodated to the state of science, and are instances of a false system which has materially contributed to the establishment of truth.

2. Copernicus and Tycho.

On the revival of learning in Europe, astronomy was the first of the sciences which was regenerated. Such, indeed, is the beauty and usefulness of this branch of knowledge, that, in the thickest darkness of the middle ages, the study of it was never entirely abandoned. In those times of ignorance, it also derived additional credit from the assistance which it seemed to give to an imaginary and illusive science. Astrology, which has exercised so durable and extensive a dominion over the human mind, is coëval with the first observations of astronomy. In the middle ages, remarkable for the mixture of a few fragments of knowledge and truth in a vast mass of ignorance and error, it was assiduously cultivated, and, in conjunction with alchemy and magic, shared the favour of the people, and the patronage of the great. During the thirteenth and fourteenth centuries, it was taught in the universities of Italy, and professors were appointed, at Padua and Bologna, to instruct their pupils in the influence of the stars. Everywhere through Europe the greatest respect was shown for this system of imposture, and they who saw the deceit most clearly, could not always avoid the disgrace of being the instruments of it. Astronomy, however, profited by the illusion, and was protected for the great assistance which it seemed to afford to a science more important than itself.

Of those who cultivated astronomy, many were infected by this weakness, though some were completely superior to it. Alphonso, the King of Castile, was among the latter. He flourished about the middle of the thirteenth century, and was remarkable for such freedom of thought, and such boldness of language, as it required his royal dignity to protect. He applied himself diligently to the study of astronomy; he perceived the inaccuracy of Ptolemy's tables, and endeavoured to correct their errors by new tables of his own. These, in the course of the next age, were found to have receded from the heavens, and it became more and more evident that astronomers had not yet discovered the secret of the celestial motions.

Two of the men who, in the fifteenth century, contributed the most to the advancement of astronomical science, Purbach and Regiomontanus, were distinguished also for their general knowledge of the mathematics. Purbach was fixed at Vienna by the patronage of the Emperor Frederick the Third, and devoted himself to astronomical observation. He published a new edition of the *Almagest*, and, though he neither under-

stood Greek nor Arabic, his knowledge of the subject enabled him to make it much more perfect than any of the former translations. He is said to have been the first who applied the plummet to astronomical instruments; but this must not be understood strictly, for some of Ptolemy's instruments, the parallactic for instance, were placed perpendicularly by the plumb-line.

Regiomontanus was the disciple of Purbach, and is still more celebrated than his master. He was a man of great learning and genius, most ardent for the advancement of knowledge, and particularly devoted to astronomy. To him we owe the introduction of decimal fractions, which completed our arithmetical notation, and formed the second of the three steps by which, in modern times, the science of numbers has been so greatly improved.

In the list of distinguished astronomers, the name of Copernicus comes next, and stands at the head of those men, who, bursting the fetters of prejudice and authority, have established truth on the basis of experience and observation. He was born at Thorn in Prussia, in 1473; he studied at the university of Cracow, being intended at first for a physician, though he afterwards entered into the church. A decided taste for astronomy led him early to the study of the science in which he was destined to make such an entire revolution, and as soon as he found himself fixed and independent, he became a diligent and careful observer.

It would be in the highest degree interesting to know by what steps he was led to conceive the bold system which removes the earth from the centre of the world, and ascribes to it a twofold motion. It is probable that the complication of so many epicycles and deferents as were necessary, merely to express the laws of the planetary motions, had induced him to think of all the possible suppositions which could be employed for the same purpose, in order to discover which of them was the simplest.

It appears extraordinary, that so natural a thought should have occurred, at so late a period, for the first, or nearly for the first time. We are assured, by Copernicus himself, that one of the first considerations which offered itself to his mind, was the effect produced by the motion of a spectator, in transferring that motion to the objects observed, but ascribing to it an opposite direction.[1] From this principle it immediately followed, that the rotation of the earth on an axis, from west to east, would produce the apparent motion of the heavens in the direction from east to west.

---

[1] Astronomia Instaurata, Lib. I. cap. 5.

In considering some of the objections which might be made to the system of the earth's motion, Copernicus reasons with great soundness, though he is not aware of the full force of his own argument. Ptolemy had alleged, that, if the earth were to revolve on its axis, the violence of the motion would be sufficient to tear it in pieces, and to dissipate the parts. This argument, it is evident, proceeds on a confused notion of a centrifugal force, the effect of which the Egyptian astronomer overrated, as much as he undervalued the firmness and solidity of the earth. Why, says Copernicus, was he not more alarmed for the safety of the heavens, if the diurnal revolution be ascribed to them, as their motion must be more rapid, in proportion as their magnitude is greater? The argument here suggested, now that we know how to measure centrifugal force, and to compare it with others, carries demonstrative evidence with it, because that force, if the diurnal revolution were really performed by the heavens, would be such, as the forces which hold together the frame of the material world would be wholly unable to resist.

There are, however, in the reasonings of Copernicus, some unsound parts, which show, that the power of his genius was not able to dispel all the clouds which in that age hung over the human mind, and that the unfounded distinctions of the Aristotelian physics sometimes afforded arguments equally fallacious to him and to his adversaries. One of his most remarkable physical mistakes was his misconception with respect to the parallelism of the earth's axis; to account for which, he thought it necessary to assume, in addition to the earth's rotation on an axis, and revolution round the sun, the existence of a third motion altogether distinct from either of the others. In this he was mistaken; the axis naturally retains its parallelism, and it would require the action of a force to make it do otherwise. This, as Kepler afterwards remarked, is a consequence of the *inertia* of matter; and, for that reason, he very justly accused Copernicus of not being fully acquainted with his own riches.

The first edition of the *Astronomia Instaurata*, the publication of which was solicited by Cardinal Schoenberg, and the book itself dedicated to the Pope, appeared in 1543, a few days before the death of the author. Throughout the whole book, the new doctrine was advanced with great caution, as if from a presentiment of the opposition and injustice which it was one day to experience. At first, however, the system attracted little notice, and was rejected by the greater part even of astronomers. It lay fermenting in secret with other new discoveries for more than fifty years, till, by the exertions of Galileo, it was kindled into so bright a flame as to consume the philosophy of Aristotle, to alarm the hierarchy of Rome, and to threaten the existence of every opinion not founded on experience and observation.

After Copernicus, Tycho Brahé was the most distinguished astronomer of the six-

teenth century. An eclipse of the sun which he witnessed in 1560, when he was yet a very young man, by the exactness with which it answered to the prediction, impressed him with the greatest reverence for a science which could see so far and so distinctly into the future, and from that moment he was seized with the strongest desire of becoming acquainted with it. Here, indeed, was called into action a propensity nearly allied both to the strength and the weakness of the mind of this extraordinary man, the same that attached him, on one hand, to the calculations of astronomy, and, on the other, to the predictions of judicial astrology.

In yielding himself up, however, to his love of astronomy, he found that he had several difficulties to overcome. He belonged to a class in society elevated, in the opinion of that age, above the pursuit of knowledge, and jealous of the privilege of remaining ignorant with impunity. Tycho was of a noble family in Denmark, so that it required all the enthusiasm and firmness inspired by the love of knowledge, to set him above the prejudices of hereditary rank, and the opposition of his relations. He succeeded, however, in these objects, and also in obtaining the patronage of the King of Denmark, by which he was enabled to erect an observatory, and form an establishment in the island of Huena, such as had never yet been dedicated to astronomy. The instruments were of far greater size, more skilfully contrived, and more nicely divided, than any that had yet been directed to the heavens. By means of them, Tycho could measure angles to ten seconds, which may be accounted sixty times the accuracy of the instruments of Ptolemy, or of any that had belonged to the school of Alexandria.

Among the improvements which he made in the art of astronomical observation, was that of verifying the instruments, or determining their errors by actual observation, instead of trusting, as had been hitherto done, to the supposed infallibility of the original construction.

One of the first objects to which the Danish astronomer applied himself was the formation of a new catalogue of the fixed stars. That which was begun by Hipparchus, and continued by Ptolemy, did not give the places of the stars with an accuracy nearly equal to that which the new instruments were capable of reaching; and it was besides desirable to know whether the lapse of twelve centuries had produced any unforeseen changes in the heavens.

The great difficulty in the execution of this work arose from the want of a direct and easy method of ascertaining the distance of one heavenly body due east or west of another. The distance north or south, either from one another or from a fixed plane, that of the equator, was easily determined by the common method of meridian altitudes, the

equator being a plane which, for any given place on the earth's surface, retains always the same position. But no plane extending from north to south, or passing through the poles, retains a fixed position with respect to an observer, and, therefore, the same way of measuring distances from such a plane cannot be applied. The natural substitute is the measure of time; the interval between the passage of two stars over the meridian, bearing the same proportion to twenty-four hours, that the arch which measures their distance perpendicular to the meridian, or their difference of right ascension, does to four right angles.

An accurate measure of time, therefore, would answer the purpose, but such a measure no more existed in the age of Tycho, than it had done in the days of Hipparchus or Ptolemy. These ancient astronomers determined the longitude of the fixed stars by referring their places to those of the moon, the longitude of which, for a given time, was known from the theory of her motions. Thus they were forced to depend on the most irregular of all the bodies in the heavens, for ascertaining the positions of the most fixed, those which ought to have been the basis of the former, and of so many other determinations. Tycho made use of the planet Venus instead of the moon, and his method, though more tedious, was more accurate than that of the Greek astronomers. His catalogue contained the places of 777 fixed stars.

The irregularities of the moon's motions were his next subjects of inquiry. The ancients had discovered the inequality of that planet depending on the eccentricity of the orbit, the same which is now called the equation of the centre.[1] Ptolemy had added the knowledge of another inequality in the moon's motion, to which the name of the evection has been given, amounting to an increase of the former equation at the quarters, and a diminution of it at the times of new and full moon. Tycho discovered another inequality, which is greatest at the octants, and depends on the difference between the longitude of the moon and that of the sun. A fourth irregularity to which the moon's motion is subject, depending wholly on the sun's place, was known to Tycho, but included among the sun's equations. Besides, these observations made him acquainted with the changes in the inclination of the plane of the moon's orbit; and, lastly, with the irregular motion of the nodes, which, instead of being always retrograde at the same rate, are subject to change that rate, and even to become progressive according to their situation in

[1] The allowance made for any such equality, when the place of a planet is to be computed for a given time, is called an *equation* in the language of astronomy.

respect of the sun. These are the only inequalities of the moon's motion known before the theory of Gravitation, and, except the two first, are all the discoveries of Tycho.

The atmospherical refraction, by which the heavenly bodies are made to appear more elevated above the horizon than they really are, was suspected before the time of this astronomer, but not known with certainty to exist. He first became acquainted with it by finding that the latitude of his observatory, as determined from observations at the solstices, and from observations of the greatest and least altitudes of the circumpolar stars, always differed about four minutes. The effect of refraction he supposed to be 34′ at the horizon, and to diminish from thence upward, till at 45° it ceased altogether. This last supposition is erroneous, but at 45° the refraction is less than 1′, and probably was not sensible in the altitudes measured with his instruments, or not distinguishable from the errors of observation. An instrument which he contrived on purpose to make the refraction distinctly visible, shows the scale on which his observatory was furnished. It was an equatorial circle of ten feet diameter, turning on an axis parallel to that of the earth. With the sights of this equatorial he followed the sun on the day of the summer solstice, and found, that, as it descended towards the horizon, it rose above the plane of the instrument. At its setting, the sun was raised above the horizon by more than its own diameter.

The comet of 1570 was carefully observed by Tycho, and gave rise to a new theory of those bodies. He found the horizontal parallax to be 20′, so that the comet was nearly three times as far off as the moon. He considered comets, therefore, as bodies placed far beyond the reach of our atmosphere, and moving round the sun. This was a severe blow to the physics of Aristotle, which regarded comets as meteors generated in the atmosphere. His observation of the new star in 1572, was no less hostile to the argument of the same philosopher, which maintained, that the heavens are a region in which there is neither generation nor corruption, and in which existence has neither a beginning nor an end.

Yet Tycho, with this knowledge of astronomy, and after having made observations more numerous and accurate than all the astronomers who went before him, continued to reject the system of Copernicus, and to deny the motion of the earth. He was, however, convinced that the earth is not the centre about which the planets revolve, for he had himself observed Mars, when in opposition, to be nearer to the earth than the earth was to the sun, so that, if the planets were ranged as in the Ptolemaic system, the orbit of Mars must have been within the orbit of the sun. He therefore imagined the system still known by his name, according to which the sun moves round the earth, and is at the same time

the centre of the planetary motions. It cannot be denied, that the phenomena purely astronomical may be accounted for on this hypothesis, and that the objections to it are rather derived from physical and mechanical considerations than from the appearances themselves. It is simpler than the Ptolemaic system, and free from its inconsistencies ; but it is more complex than the Copernican, and, in no respect, affords a better explanation of the phenomena. The true place of the Tychonic system is between the two former ; an advance beyond the one, and a step short of the other ; and such, if the progress of discovery were always perfectly regular, is the place which it would have occupied in the history of the science. If Tycho had lived before Copernicus, his system would have been a step in the advancement of knowledge ; coming after him, it was a step backward.

It is not to his credit as a philosopher to have made this retrograde movement, yet he is not altogether without apology. The physical arguments in favour of the Copernican system, founded on the incongruity of supposing the greater body to move round the smaller, might not be supposed to have much weight, in an age when the equality of action and reaction was unknown, and when it was not clearly understood that the sun and the planets act at all on one another. The arguments, which seem, in the judgment of Tycho, to have balanced the simplicity of the Copernican system, were founded on certain texts of Scripture, and on the difficulty of reconciling the motion of the earth with the sensations which we experience at its surface, or the phenomena which we observe, the same, in all respects, as if the earth were at rest. The experiments and reasonings of Galileo had not yet instructed men in the *inertia* of matter, or in the composition of motion ; and the followers of Copernicus reasoned on principles which they held in common with their adversaries. A ball, it was said by the latter, dropt from the mast-head of a ship under sail, does not fall at the foot of the mast, but somewhat behind it ; and, in the same manner, a stone dropt from a high tower would not fall, on the supposition of the earth's motion, at the bottom of the tower, but to the west of it, the earth, during its fall, having gone eastward from under it. The followers of Copernicus were not yet provided with the true answer to this objection, viz. that the ball does actually fall at the bottom of the mast. It was admitted that it must fall behind it, because the ball was no part of the ship, and that the motion forward was not natural, either to the ship or to the ball. The stone, on the other hand, let fall from the top of the tower, was a part of the earth ; and, therefore, the diurnal and annual revolutions which were natural to the earth, were also natural to the stone ; the stone would, therefore, retain the same motion with the tower, and strike the ground precisely at the bottom of it.

It must be confessed, that neither of these logicians had yet thoroughly awakened from the dreams of the Aristotelian metaphysics, but men were now in possession of the truth, which was finally to break the spell, and set the mind free from the fetters of prejudice and authority. Another charge, against which it is more difficult to defend Tycho, is his belief in the predictions of astrology. He even wrote a treatise in defence of this imaginary art, and regulated his conduct continually by its precepts. Credulity, so unworthy of a man deeply versed in real science, is certainly to be set down less to his own account than to that of the age in which he lived.

3. Kepler and Galileo.

Kepler followed Tycho, and in his hands astronomy underwent a change only second to that which it had undergone in the hands of Copernicus. He was born in 1571. He early applied himself to study and observe the heavens, and was soon distinguished as an inventor. He began with taking a more accurate view of astronomical refraction than had yet been done, and he appears to have been the first who conceived that there must be a certain fixed law which determined the quantity of it, corresponding to every altitude, from the horizon to the zenith. The application of the principles of optics to astronomy, and the accurate distinction between the optical and real inequalities of the planets, are the work of the same astronomer. It was by the views thus presented that he was led to the method of constructing and calculating eclipses, by means of projections, without taking into consideration the diurnal parallax. These are valuable improvements, but they were, however, obscured by the greatness of his future discoveries.

The planes of the orbits of the planets were naturally, in the Ptolemaic system, supposed to pass through the earth, and the reformation of Copernicus did not go so far as to change the notions on that subject which had generally been adopted. Kepler observed that the orbits of the planets are in planes passing through the sun, and that, of consequence, the lines of their nodes all intersect in the centre of that luminary. This discovery contributed essentially to those which followed.

The oppositions of the planets, or their places when they pass the meridian at midnight, offer the most favourable opportunities for observing them, both because they are at that time nearest to the earth, and because their places seen from thence is the same as if they were seen from the sun. The true time of the opposition had, however, been till now mistaken by astronomers, who held it to be at the moment when the apparent place of the planet was opposite to the mean place of the sun. It ought, however,

to have been, when the apparent places of both were opposed to one another. This reformation was proposed by Kepler, and, though strenuously resisted by Tycho, was finally received.

Having undertaken to examine the orbit of Mars, in which the irregularities are most considerable, Kepler discovered, by comparing together seven oppositions of that planet, that its orbit is elliptical; that the sun is placed in one of the foci; and that there is no point round which the angular motion is uniform. In the pursuit of this inquiry he found that the same thing is true of the earth's orbit round the sun; hence by analogy it was reasonable to think, that all the planetary orbits are elliptical, having the sun in their common focus.

The industry and patience of Kepler, in this investigation, were not less remarkable than his ingenuity and invention. Logarithms were not yet known, so that arithmetical computation, when pushed to great accuracy, was carried on at a vast expence of time and labour. In the calculation of every opposition of Mars, the work filled ten folio pages, and Kepler repeated each calculation ten times, so that the whole work for each opposition extended to one hundred such pages; seven oppositions thus calculated produced a large folio volume.

In these calculations the introduction of hypotheses was unavoidable, and Kepler's candour in rejecting them, whenever they appeared erroneous, without any other regret than for the time which they had cost him, cannot be sufficiently admired. He began with hypothesis, and ended with rejecting every thing hypothetical. In this great astronomer we find genius, industry, and candour, all uniting together as instruments of investigation.

Though the angular motion of the planet was not found to be uniform, it was discovered that a very simple law connected that motion with the rectilineal distance from the sun, the former being every where inversely as the square of the latter; and hence it was easy to prove, that the area described by the line drawn from the planet to the sun increased at a uniform rate, and, therefore, that any two such areas were proportional to the times in which they were described. The picture presented of the heavens was thus, for the first time, cleared of every thing hypothetical.

The same astronomer was perhaps the first person who conceived that there must be always a law capable of being expressed by arithmetic or geometry, which connects such phenomena as have a physical dependence on one another. His conviction of this truth, and the delight which he appears to have experienced in the contemplation of such laws, led him to seek, with great eagerness, for the relation between the periodical times of the planets, and their distances from the sun. He seems, indeed, to have looked towards this

object with such earnestness, that, while it was not attained, he regarded all his other discoveries as incomplete. He at last found, infinitely to his satisfaction, that in any two planets, the squares of the times of the revolution are as the cubes of their mean distances from the sun. This beautiful and simple law had a value beyond what Kepler could possibly conceive; yet a sort of scientific instinct instructed him in its great importance. He has marked the year and the day when it became known to him; it was on the 8th of May 1618; and perhaps philosophers will agree that there are few days in the scientific history of the world which deserve so well to be remembered.

These great discoveries, however, were not much attended to by the astronomers of that period, or by those who immediately followed. They were but little considered by Gassendi,—they were undervalued by Riccioli,—and were never mentioned by Descartes. It was an honour reserved for Newton to estimate them at their true value.

Indeed, the discoveries of Kepler were at first so far from being duly appreciated, that they were objected to, not for being false, but for offering to astronomers, in the calculation of the place of a planet in its orbit, a problem too difficult to be resolved by elementary geometry. To cut the area of a semi-ellipsis in a given ratio by a line drawn through the focus, is the geometrical problem into which he showed that the above inquiry ultimately resolved. As if he had been answerable for the proceedings of nature, the difficulty of this question was considered as an argument against his theory, and he himself seems somewhat to have felt it as an objection, especially when he found that the best solution he could obtain was no more than an approximation. With all his power of invention, Kepler was a mathematician inferior to many of that period; and though he displayed great ability in the management of this difficult investigation, his solution fell very far short of the simplicity which it was afterwards found capable of attaining.

In addition to all this, he rendered another very important service to the science of astronomy and to the system of Copernicus. Copernicus, it has been already mentioned, had supposed that a force was necessary to enable the earth to preserve the parallelism of its axis during its revolution round the sun. He imagined, therefore, that a third motion belonged to the earth, and that, besides turning on its axis and revolving round the sun, it had another movement by which its axis was preserved always equally inclined to the ecliptic. Kepler was the first to observe that this third motion was quite superfluous, and that the parallelism of the earth's axis, in order to be preserved, required nothing but the absence of all force, as it necessarily proceeded from the inertia of matter, and its tendency to persevere in a state of uniform motion. Kepler had a clear idea of the inertia of body; he was the first who employed the term; and,

considering all motion as naturally rectilineal, he concluded that when a body moves in a curve, it is drawn or forced out of the straight line by the action of some cause, not residing in itself. Thus he prepared the way for physical astronomy, and in these ideas he was earlier than Descartes.

The discoveries of Kepler were secrets extorted from nature by the most profound and laborious research. The astronomical discoveries of Galileo, more brilliant and imposing, were made at a far less expence of intellectual labour. By this it is not meant to say that Galileo did not possess, and did not exert intellectual powers of the very highest order, but it was less in his astronomical discoveries that he had occasion to exert them, than in those which concerned the theory of motion. The telescope turned to the heavens for the first time, in the hands of a man far inferior to the Italian philosopher, must have unfolded a series of wonders to astonish and delight the world.

It was in the year 1609 that the news of a discovery, made in Holland, reached Galileo, viz. that two glasses had been so combined, as greatly to magnify the objects seen through them. More was not told, and more was not necessary to awaken a mind abundantly alive to all that interested the progress either of science or of art. Galileo applied himself to try various combinations of lenses, and he quickly fell on one which made objects appear greater than when seen by the naked eye, in the proportion of three to one. He soon improved on this construction, and found one which magnified thirty-two times, nearly as much as the kind of telescope he used is capable of. That telescope was formed of two lenses; the lense next the object convex, the other concave; the objects were presented upright, and magnified in their lineal dimensions in the proportion just assigned.

Having tried the effect of this combination on terrestrial objects, he next directed it to the moon. What the telescope discovers on the ever-varying face of that luminary, is now well known, and needs not to be described; but the sensations which the view must have communicated to the philosopher who first beheld it, may be conceived more easily than expressed. To the immediate impression which they made upon the sense, to the wonder they excited in all who saw them, was added the proof, which, on reflection, they afforded, of the close resemblance between the earth and the celestial bodies, whose divine nature had been so long and so erroneously contrasted with the ponderous and opaque substance of our globe. The earth and the planets were now proved to be bodies of the same kind, and views were entertained of the universe, more suitable to the simplicity and the magnificence of nature.

When the same philosopher directed his telescope to the fixed stars, if he was disap-

pointed at finding their magnitudes not increased, he was astonished and delighted to find them multiplied in so great a degree, and such numbers brought into view, which were invisible to the naked eye. In Jupiter he perceived a large disk, approaching in size to the moon. Near it, as he saw it for the first time, were three luminous points ranged in a straight line, two of them on one side of the planet, and one on the other. This occasioned no surprise, for they might be small stars not visible to the naked eye, such as he had already discovered in great numbers. By observing them, however, night after night, he found these small stars to be four in number, and to be moons or satellites, accompanying Jupiter, and revolving round him, as the moon revolves round the earth.

The eclipses of these satellites, their conjunctions with the planet, their disappearance behind his disk, their periodical revolutions, and the very problem of distinguishing them from one another, offered, to an astronomer, a series of new and interesting observations.

In Saturn he saw one large disk, with two smaller ones very near it, and diametrically opposite, and always seen in the same places; but more powerful telescopes were required before these appearances could be interpreted.

The horned figure of Venus, and the gibbosity of Mars, added to the evidence of the Copernican system, and verified the conjectures of its author, who had ventured to say, that, if the sense of sight were sufficiently powerful, we should see Mercury and Venus exhibiting phases similar to those of the moon.

The spots of the sun derived an interest from their contrast with the luminous disk over which they seemed to pass. They were found to have such regular periods of return, as could be derived only from the motion of the disk itself; and thus the sun's revolution on his axis, and the time of that revolution, were clearly ascertained.

This succession of noble discoveries, the most splendid, probably, which it ever fell to the lot of one individual to make, in a better age would have entitled its author to the admiration and gratitude of the whole scientific world, but was now viewed from several quarters with suspicion and jealousy. The ability and success with which Galileo had laboured to overturn the doctrines of Aristotle and the schoolmen, as well as to establish the motion of the earth, and the immobility of the sun, had excited many enemies. There are always great numbers who, from habit, indolence, or fear, are the determined supporters of what is established, whether in practice or in opinion. To these the constitution of the universities of Europe, so entirely subjected to the church, had added a numerous and learned phalanx, interested to preserve the old systems, and to resist all innovations which could endanger their authority or their repose. The church itself was roused to action,

by reflecting that it had staked the infallibility of its judgments on the truth of the very opinions which were now in danger of being overthrown. Thus was formed a vast combination of men, not very scrupulous about the means which they used to annoy their adversaries; the power was entirely in their hands, and there was nothing but truth and reason to be opposed to it.

The system of Copernicus, however, while it remained obscure, and known only to astronomers, created no alarm in the church. It had even been ushered into the world at the solicitation of a cardinal, and under the patronage of the Pope; but when it became more popular, when the ability and acuteness of Galileo were enlisted on its side, the consequences became alarming; and it was determined to silence by force an adversary who could not be put down by argument. His dialogues contained a full exposition of the evidence of the earth's motion, and set forth the errors of the old, as well as the discoveries of the new philosophy, with great force of reasoning, and with the charms of the most lively eloquence. They are written, indeed, with such singular felicity, that one reads them at the present day, when the truths contained in them are known and admitted, with all the delight of novelty, and feels one's self carried back to the period when the telescope was first directed to the heavens, and when the earth's motion, with all its train of consequences, was proved for the first time. The author of such a work could not be forgiven. Galileo, accordingly, was twice brought before the Inquisition. The first time a council of seven cardinals pronounced a sentence which, for the sake of those disposed to believe that power can subdue truth, ought never to be forgotten: "That to maintain the sun to be immoveable, and without local motion, in the centre of the world, is an absurd proposition, false in philosophy, heretical in religion, and contrary to the testimony of Scripture. That it is equally absurd and false in philosophy to assert that the earth is not immoveable in the centre of the world, and, considered theologically, equally erroneous and heretical."

These seven theologians might think themselves officially entitled to decide on what was heretical or orthodox in faith, but that they should determine what was true or false in philosophy, was an insolent invasion of a territory into which they had no right to enter, and is a proof how ready men are to suppose themselves wise, merely because they happen to be powerful. At this time a promise was extorted from Galileo, that he would not teach the doctrine of the earth's motion, either by speaking or by writing. To this promise he did not conform. His third dialogue, published, though not till long afterwards, contained such a full display of the beauty and simplicity of the new system, and

such an exposure of the inconsistencies of Ptolemy and Tycho, as completed the triumph of Copernicus.

In the year 1663, Galileo, now seventy years old, being brought before the Inquisition, was forced solemnly to disavow his belief in the earth's motion; and condemned to perpetual imprisonment, though the sentence was afterwards mitigated, and he was allowed to return to Florence.[1] The Court of Rome was very careful to publish this second recantation all over Europe, thinking, no doubt, that it was administering a complete antidote to the belief of the Copernican system. The sentence, indeed, appears to have pressed very heavily on Galileo's mind, and he never afterwards either talked or wrote on the subject of astronomy. Such was the triumph of his enemies, on whom ample vengeance would have long ago been executed, if the indignation and contempt of posterity could reach the mansions of the dead.

Conduct like this, in men professing to be the ministers of religion and the guardians of truth, can give rise to none but the most painful reflections. That an aged philosopher should be forced, laying his hand on the sacred Scriptures, to disavow opinions which he could not cease to hold without ceasing to think, was as much a profanation of religion, as a violation of truth and justice. Was it the act of hypocrites, who considered religion as a state engine, or of bigots, long trained in the art of believing without evidence, or even in opposition to it? These questions it were unnecessary to resolve; but one conclusion cannot be denied, that the indiscreet defenders of religion have often proved its worst enemies.

At length, however, by the improvements, the discoveries, and the reasonings, first of Kepler, and then of Galileo, the evidence of the Copernican system was fully developed, and nothing was wanting to its complete establishment, but time sufficient to allow opinion to come gradually round, and to give men an opportunity of studying the arguments placed before them. Of the adherents of the old system, many had been too long habituated to it to change their views; but as they disappeared from the scene, they were replaced by young astronomers, not under the influence of the same prejudices, and eager to follow doctrines which seemed to offer so many new subjects of investigation. In the next generation the systems of Ptolemy and Tycho had no followers.

It was not astronomy alone which was benefited by this revolution, and the discussions to which it had given rise. A new light, as already remarked, was thrown on the phy-

---

[1] He was thrown into prison previously to his trial, and attempts were made to render him obnoxious to the people. From the text of a priest who preached against him, we may judge of the wit and the sense with which this persecution was conducted. *Viri Galilæi quid statis in cælum suspicientes?*

sical world, and the curtain was drawn aside which had so long concealed the great experiment, by which nature herself manifests, at every instant, the inertia of body, and the composition of forces. To reconcile the real motion of the earth with its appearance of rest, and with our feeling of its immobility, required such an examination of the nature of motion, as discovered, if not its essence, at least its most general and fundamental properties. The whole science of rational mechanics profited, therefore, essentially by the discovery of the earth's motion.

A great barrier to philosophic improvement had arisen from the separation so early made, and so strenuously supported in the ancient systems, between terrestrial and celestial substances, and between the laws which regulate motion on the earth, and in the heavens. This barrier was now entirely removed; the earth was elevated to the rank of a planet; the planets were reduced to the condition of earths, and by this mutual approach, the same rules of interpretation became applicable to the phenomena of both. Principles derived from experiments on the earth, became guides for the analysis of the heavens, and men were now in a situation to undertake investigations, which the most hardy adventurer in science could not before have dared to imagine. Philosophers had ascended to the knowledge of the affinities which pervade all nature, and which mark so strongly both the wisdom and unity of its author.

The light thus struck out darted its rays into regions the most remote from physical inquiry. When men saw opinions entirely disproved, which were sanctioned by all antiquity, and by the authority of the greatest names, they began to have different notions of the rules of evidence, of the principles of philosophic inquiry, and of the nature of the mind itself. It appeared that science was destined to be continually progressive; provided it was taken for an inviolable maxim, that all opinion must be ultimately amenable to experience and observation.

It was no slight addition to all these advantages, that, in consequence of the discussions from which Galileo had unhappily been so great a sufferer, the line was at length definitely drawn which was to separate the provinces of faith and philosophy from one another. It became a principle, recognised on all hands, that revelation, not being intended to inform men of those things which the unassisted powers of their own understanding would in time be able to discover, had, in speaking of such matters, employed the language and adopted the opinions of the times; and thus the magic circle by which the priest had endeavoured to circumscribe the inquiries of the philosopher entirely disappeared. The reformation in religion which was taking place about the same time, and giving such energy to the human mind, contributed to render this emancipation more

complete, and to reduce the exorbitant pretensions of the Romish church. The prohibition against believing in the true system of the world either ceased altogether, or was reduced to an empty form, by which the affectation of infallibility still preserves the memory of its errors.[1]

4. Descartes, Huygens, &c.

Descartes flourished about this period, and has the merit of being the first who undertook to give an explanation of the celestial motions, or who formed the great and philosophic conception of reducing all the phenomena of the universe to the same law. The time was now arrived when, from the acknowledged assimilation of the planets to the earth, this might be undertaken with some reasonable prospect of success. No such attempt had hitherto been made, unless the crystalline spheres or homocentric orbs of the ancients are to be considered in that light. The conjectures of Kepler about a kind of animation, and of organic structure, which pervaded the planetary regions, were too vague and indefinite, and too little analogous to any thing known on the earth, to be entitled to the name of a theory. To Descartes, therefore, belongs the honour of being the first who ventured on the solution of the most arduous problem which the material world offers to the consideration of philosophy. For this solution he sought no other data than *matter* and *motion*, and with them alone proposed to explain the structure and constitution of the universe. The matter which he required, too, was of the simplest kind, possessing no properties but extension, impenetrability, and inertia. It was matter in the abstract, without any of its peculiar or distinguishing characters. To explain these characters, was indeed a part of the task which he proposed to himself, and thus, by the simplicity of his assumptions, he added infinitely to the difficulty of the problem which he undertook to resolve.

The matter thus constituted was supposed to fill all space, and its parts, both great and small, to be endued with motion in an infinite variety of directions. From the combination of these, the rectilineal motion of the parts become impossible; the atoms or particles of matter were continually diverted from the lines in which they had begun

---

[1] The learned fathers who have, with so much ability, commented on the *Principia* of Newton, have prefixed to the third book this remarkable declaration :—" Newtonus in hoc tertio libro telluris motæ hypothesin assumit. Auctoris propositiones aliter explicari, non poterant nisi eâdam factâ hypothesi. Hinc alienam coacti sumus gerere personam. *Ceterum latis a summis Pontificibus contra telluris motum Decretis nos obsequi profitemur.*" There is an archness in the last sentence, that looks as if the authors wanted to convey meanings that would differ according to the orthodoxy of the readers.

to move; so that circular motion and centrifugal force originated from their action on one another. Thus matter came to be formed into a multitude of vortices, differing in extent, in velocity, and in density; the more subtile parts constituting the real vortex, in which the denser bodies float, and by which they are pressed, though not equally, on all sides.

Thus the universe consists of a multitude of vortices, which limit and circumscribe one another. The earth and the planets are bodies carried round in the great vortex of the solar system; and by the pressure of the subtile matter, which circulates with great rapidity, and great centrifugal force, the denser bodies, which have less rapidity, and less centrifugal force, are forced down toward the sun, the centre of the vortex. In like manner, each planet is itself the centre of a smaller vortex, by the subtile matter of which the phenomena of gravity are produced, just as with us at the surface of the earth.

The gradation of smaller vortices may be continued in the same manner, to explain the cohesion of the grosser bodies, and their other sensible qualities. But I forbear to enter into the detail of a system, which is now entirely exploded, and so inconsistent with the views of nature which have become familiar to every one, that such details can hardly be listened to with patience. Indeed, the theory of vortices did not explain a single phenomenon in a satisfactory manner, nor is there a truth of any kind which has been brought to light by means of it. None of the peculiar properties of the planetary orbits were taken into the account; none of the laws of Kepler were considered; nor was any explanation given of those laws, more than of any other that might be imagined. The philosophy of Descartes could explain all things equally well, and might have been accommodated to the systems of Ptolemy or Tycho, just as well as to that of Copernicus. It forms, therefore, no link in the chain of physical discovery; it served the cause of truth only by exploding errors more pernicious than its own; by exhausting a source of deception, which might have misled other adventurers in science, and by leaving a striking proof how little advancement can be made in philosophy, by pursuing any path but that of experiment and induction. Descartes was, nevertheless, a man of great genius, a deep thinker, of enlarged views, and entirely superior to prejudice. Yet, in as far as the explanation of astronomical phenomena is concerned (and it was his main object), he did good only by showing in what quarter the attempt could not be made with success; he was the forlorn hope of the new philosophy, and must be sacrificed for the benefit of those who were to follow.

Gassendi, the contemporary and countryman of Descartes, possessed great learning, with a very clear and sound understanding. He was a good observer, and an enlightened

advocate of the Copernican system. He explained, in a very satisfactory manner, the connection between the laws of motion and the motion of the earth, and made experiments to show, that a body carried along by another acquires a motion which remains after it has ceased to be so carried. Gassendi first observed the transit of a planet over the disk of the sun,—that of Mercury, in 1631. Kepler had predicted this transit, but did not live to enjoy a spectacle which afforded so satisfactory a proof of the truth of his system, and of the accuracy of his astronomical tables.

The first transit of Venus, which was observed, happened a few years later, in 1639, when it was seen in England by Horrox, and his friend Crabtree, and by them only. Horrox, who was a young man of great genius, had himself calculated the transit, and foretold the time very accurately, though the astronomical tables of that day gave different results, and those of Kepler, in which he confided the most, were, in this instance, considerably in error. Horrox has also the merit of being among the first who rightly appreciated the discoveries of the astronomer just named. He had devoted much time to astronomical observation, and, though he died very young, he left behind him some preparations for computing tables of the moon, on a principle which was new, and which Newton himself thought worthy of being adopted in his theory of the inequalities of that planet.

The first complete system of astronomy, in which the elliptic orbits were introduced, was the *Astronomia Philolaica* of Bullialdus (Bouillaud), published in 1645. They were introduced, however, with such hypothetical additions, as show that the idea of a centre of uniform motion had not yet entirely disappeared. It is an idea, indeed, which gives considerable relief to the imagination, and it besides leads to methods of calculation more simple than the true theory, and Bullialdus may have flattered himself that they were sufficiently exact. He conceives the elliptic orbit as a section of an oblique cone, the axis of which passes through the superior focus of the ellipse, while the planet moves in its circumference in such a manner, that a plane passing through it and through the axis, shall be carried round with a uniform angular velocity. It is plain that the cone and its axis are mere fictions, arbitrarily assumed, and not even possessing the advantage of simplicity. The author himself departs from this hypothesis, and calculates the places of a planet, on the supposition that it moves in the circumference of an epicycle, and the epicycle in the circumference of an eccentric deferent, both angular motions being uniform, that of the planet in the epicycle being retrograde, and double the other. The figure thus described may be shown to be an ellipse, but the line drawn from the planet to the focus does not cut off areas proportional to the time.

An hypothesis advanced by Ward, Bishop of Salisbury, was simpler and more accurate than that of the French astronomer. According to it, the line drawn from a planet to the superior focus of its elliptic orbit, turns with a uniform angular velocity round that point. In orbits of small eccentricity, this is nearly true, and almost coincides in such cases with Kepler's principle of the uniform description of areas. Dr Ward, however, did not consider the matter in that light; he assumed his hypothesis as true, guided, it would seem, by nothing but the opinion, that a centre of uniform motion must somewhere exist, and pleased with the simplicity thus introduced into astronomical calculation. It is, indeed, remarkable, as Montucla has observed, how little the most enlightened astronomers of that time seem to have studied or understood the laws discovered by Kepler. Riccioli, of whom we are just about to speak, enumerates all the suppositions that had been laid down concerning the velocities of the planets, but makes no mention of their describing equal areas in equal times round the sun. Even Cassini, great as he was in astronomy, cannot be entirely exempted from this censure.

Riccioli, a good observer, and a learned and diligent compiler, has collected all that was known in astronomy about the middle of the seventeenth century, in a voluminous work, the *New Almagest.* Without much originality, he was a very useful author, having had, as the historian of astronomy remarks, the courage and the industry to read, to know, and to abridge every thing. He was, nevertheless, an enemy to the Copernican system, and has the discredit of having measured the evidence for and against that system, not by the weight, but by the number of the arguments. The pains which he took to prop the falling edifice of deferents and epicycles, added to his misapprehending and depreciating the discoveries of Kepler, subject him to the reproach of having neither the genius to discover truth, nor the good sense to distinguish it when discovered. He was, however, a priest and a jesuit; he had seen the fate of Galileo; and his errors may have arisen from want of courage, more than from want of discernment.

Of the phenomena which the telescope in the hands of Galileo had made known, the most paradoxical were those exhibited by Saturn; sometimes attended by two globes, one on each side, without any relative motion, but which would, at stated times, disappear for a while, and leave the planet single, like the other heavenly bodies. Nearly forty years had elapsed, without any farther insight into these mysterious appearances, when Huygens began to examine the heavens with telescopes of his own construction, better and more powerful than any which had yet been employed. The two globes that had appeared insulated, were now seen connected by a circular and luminous belt, going quite round the planet. At last, it was found that all these appearances resulted from a broad ring surrounding

Saturn, and seen obliquely from the earth. The gradual manner in which this truth unfolded itself is very interesting, and has been given with the detail that it deserves by Huygens, in his *Systema Saturnium.*

The attention which Huygens had paid to the ring of Saturn, led him to the discovery of a satellite of the same planet. His telescopes were not powerful enough to discover more of them than one; he believed, indeed, that there were no more, and that the number of the planets now discovered was complete. The reasoning by which he convinced himself, is a proof how slowly men are cured of their prejudices, even with the best talents and the best information. The planets, primary and secondary, thus made up twelve, the double of six, the first of the perfect numbers. In 1671, however, Cassini discovered another satellite, and afterwards three more, making five in all, which the more perfect telescopes of Dr Herschell have lately augmented to seven.

To the genius of Huygens astronomy is indebted for an addition to its apparatus, hardly less essential than the quadrant and the telescope. An accurate measure of time is of use even in the ordinary business of life, but to the astronomer is infinitely valuable. The dates of his observations, and an accurate estimate of the time elapsed between them, is necessary, in order to make them lead to any useful consequences. Besides this, the only way of measuring with accuracy those arches in the heavens, which extend from east to west, or which are parallel to the equator, depends on the earth's rotation, because such an arch bears the same proportion to the entire circumference of a circle, that the time of its passage under the meridian bears to an entire day. The reckoning of time thus furnishes the best measure of position, as determined by arches parallel to the equator, whether on the earth or in the heavens.

Though the pendulum afforded a measure of time, in itself of the greatest exactness, the means of continuing its motion, without disturbing the time of its vibrations, was yet required to be found, and this, by means of the clock, Huygens contrived most ingeniously to effect. Each vibration of the pendulum, by means of an arm at right angles to it, allows the tooth of a wheel to escape, the wheel being put in motion by a weight. The wheel is so contrived, that the force with which it acts is just sufficient to restore to the pendulum the motion which it had lost by the resistance of the air, and the friction at the centre of motion. Thus the motion of the clock is continued without any diminution of its uniformity, for any length of time.

The telescope had not yet served astronomy in all the capacities in which it could be useful. Huygens, of whose inventive genius the history of science has so much to record, applied it to the measurement of small angles, forming it into the instrument which has

since been called a micrometer. By introducing into the focus of the telescope a round aperture of a given size, he contrived to measure the angle which that aperture subtended to the eye, by observing the time that a star placed near the equator required to traverse it. When the angle subtended by any other object in the telescope was to be measured, he introduced into the focus a thin piece of metal, just sufficient to cover the object in the focus. The proportion of the breadth of this plate, to the diameter of the aperture formerly measured, gave the angle subtended by the image in the focus of the telescope. This contrivance is described in the *Systema Saturnium,* at the end.

The telescope has farther contributed materially to the accuracy of astronomical observation, by its application to instruments used for measuring, not merely small angles, but angles of any magnitude whatever. The telescope here comes in place of the plain sights with which the index or *allidad* of an instrument used to be directed to an object, and this substitution has been accompanied with two advantages. The disk of a star is never so well defined to the naked eye as it is in the telescope. Besides, in using plain sights, the eye adapts itself to the farther off of the two, in order that its aperture may be distinctly seen. Whenever this adjustment is made, the object seen through the aperture necessarily appears indistinct to the eye, which is then adapted to a near object. This circumstance produces an uncertainty in all such observations, which, by the use of the telescope, is entirely removed.

But the greatest advantage arises from the magnifying power of the telescope, from which it follows, that what is a mere point to the naked eye, is an extended line which can be divided into a great number of parts when seen through the former. The best eye, when not aided by glasses, is not able to perceive an object which subtends an angle less than half a minute, or thirty seconds. When the index of a quadrant, therefore, is directed by the naked eye to any point in the heavens, we cannot be sure that it is nearer than half a minute on either side of that point. But when we direct the axis of a telescope, which magnifies thirty times, to the same object, we are sure that it is within the thirtieth part of half a minute, that is, within one second of the point aimed at. Thus the accuracy *cæteris paribus* is proportional to the magnifying power.

The application of the telescope, however, to astronomical instruments, was not introduced without opposition. Hevelius of Dantzic, the greatest observer who had been since Tycho Brahé, who had furnished his observatory with the best and largest instruments, and who was familiar with the use of the telescope, strenuously maintained the superiority of the plain sights. His principal argument was founded on this,—that, in plain sights, the line of collimation is determined in its position by two fixed points at a considerable

distance from one another, viz. the centres of the two apertures of the sights, so that it remains invariable with respect to the index.

In the case of the telescope there was one fixed point, the intersection of the wires in the focus of the eye-glass ; but Hevelius did not think that the other point, viz. the optical centre of the object-glass, was equally well defined. This doubt, however, might have been removed by a direct appeal to experiment, or to angles actually measured on the ground, first by an instrument, and then by trigonometrical operations. From thence it would soon have been discovered, that the centre of a lens is in fact a point defined more accurately than can be done by any mechanical construction.

This method of deciding the question was not resorted to. Hevelius and Hooke had a very serious controversy concerning it, in which the advantage remained with the latter. It should have been observed that the French astronomer, Picard, was the first who employed instruments furnished with telescopic sights, about the year 1665. It appears, however, that Gascoigne, an English gentleman who fell at the battle of Marston-moor in 1644, had anticipated the French astronomer in this invention, but that it had remained entirely unknown. He had also anticipated the invention of the micrometer. The vast additional accuracy thus given to instruments formed a new era in the history of astronomical observations.

Though Galileo had discovered the satellites of Jupiter, their times of revolution, and even some of their inequalities, it yet remained to define their motions with precision, and to construct tables for calculating their places. This task was performed by the elder Cassini, who was invited from Italy, his native country, by Louis the Fourteenth, and settled in France in 1669. His tables of the satellites had been published at Bologna three years before, and he continued to improve them, by a series of observations made in the observatory at Paris, with great diligence and accuracy.

The theory of the motions of these small bodies is a research of great difficulty, and had been attempted by many astronomers before Cassini, with very little success. The planes of the orbits, their inclinations to the orbit of Jupiter, and the lines in which they intersected that orbit, were all to be determined, as well as the times of revolution, and the distances of each from its primary. Add to this, that it is only in a few points of their orbits that they can be observed with advantage. The best are at the times of immersion into the shadow of Jupiter, and emersion from it. The same excellent astronomer discovered four satellites of Saturn, in addition to that already observed by Huygens. He also discovered the rotation of Jupiter and of Mars upon their axes.

The constant attention bestowed on the eclipses of the satellites of Jupiter, made an

inequality be remarked in the periods of their return, which seemed to depend on the position of the earth relatively to Jupiter and the sun, and not, as the inequalities of that sort might have been expected to do, on the place of Jupiter in his orbit. From the opposition of Jupiter to the sun, till the conjunction, it was found, that the observed emersion of the satellites from the shadow fell more and more behind the computed; the differences amounting near the conjunction to about fourteen minutes. When, after the conjunction, the immersions were observed, an acceleration was remarked just equal to the former retardation, so that, at the opposition, the eclipse happened fourteen minutes sooner than by the calculation.

The first person who offered an explanation of these facts was Olaus Roemer, a Danish astronomer. He observed that the increase of the retardation corresponded nearly to the increase of the earth's distance from Jupiter, and conversely, the acceleration to the diminution of that distance. Hence it occurred to him, that it was to the time which light requires to traverse those distances that the whole series of phenomena was to be ascribed. This explanation was so simple and satisfactory, that it was readily received.

Though Roemer was the first who communicated this explanation to the world, yet it seems certain that it had before occurred to Cassini, and that he was prevented from making it known by a consideration which does him great honour. The explanation which the motion of light afforded, seemed not to be consistent with two circumstances involved in the phenomenon. If such was the cause of the alternate acceleration and retardation above described, why was it observed only in the eclipses of the first satellite, and not in those of the other three? This difficulty appeared so great to Cassini, that he suppressed the explanation which he would otherwise have given.

The other difficulty occurred to Maraldi. Why did not an equation or allowance of the same kind arise from the position of Jupiter, with respect to his aphelion, for, all other things being the same, his distance from the earth must be greater, as he was nearer to that point of his orbit? Both these difficulties have since been completely removed. If the aforesaid inequality was not for sometime observed in any satellite but the first, it was only because the motions of the first are the most regular, and were the soonest understood, but it now appears that the same equation belongs to all the satellites. The solution of Maraldi's difficulty is similar; for the quantity of what is called the equation of the light, is now known to be affected by Jupiter's place in his orbit.

Thus, every thing conspires to prove the reality of the motion of light, so singular on account of the immensity of the velocity, and the smallness of the bodies to which it is communicated.

5. Establishment of Academies, &c.

About the middle of the seventeenth century were formed those associations of scientific men, which, under the appellation of Academies or Philosophical Societies, have contributed so much to the advancement of knowledge in Europe. The *Academia del Cimento* of Florence, founded in 1651, carried in its name the impression of the new philosophy. It was in the country of Galileo where the first institution for the prosecution of experimental knowledge might be expected to arise, and the monuments which it has left behind it will ever create regret for the shortness of its duration.

England soon after showed the same example. It has been already remarked, that, during the civil wars, a number of learned and scientific men sought, in the retirement of Oxford, an asylum from the troubles to which the country was then a prey. They had met as early as 1645; most of them were attached to the royal cause; and after the restoration of Charles the Second, they were incorporated by a royal charter in 1662.

The first idea of this institution seems to have been suggested by the writings of Bacon, who, in recommending the use of experiment, had severely censured the schools, colleges, and academies of his own time, as adverse to the advancement of knowledge;[1] and, in the *Nova Atlantis*, had given a most interesting sketch of the form of a society, directed to scientific improvement. In Germany, the *Academia Naturæ Curiosorum* dates its commencement from 1652, and the historian of that institution ascribes the spirit

---

[1] "In moribus et institutis scholarum, academiarum, collegiorum, et similium conventuum quæ doctorum hominum sedibus et eruditionis culturæ destinata sunt, omnia progressui scientiarum adversa inveniuntur. Lectiones enim exercitia ita sunt disposita, ut aliud a consuetis haud facile cuiquam in mentem veniat cogitare, aut contemplari. Si vero unus aut alter fortasse judicii libertate uti sustinuerit, is sibi soli hanc operam imponere possit; ab aliorum autem consortio nihil capiet utilitatis. Sin et hoc toleraverit, tamen in capessenda fortuna industriam hanc et magnanimitatem sibi non levi impedimento fore experietur. Studia enim hominum in ejusmodi locis, in quorundam auctorum scripta, veluti in carceres, conclusa sunt; a quibus si quis dissentiat, continuo ut homo turbidus et rerum novarum cupidus corripitur. *In artibus autem et scientiis tanquam in metalli-fodinis omnia novis operibus et ulterioribus progressibus circumstrepere debent.*"—*Nov. Org.* lib. i. cap. 90.

It would be gratifying to be able to observe, that the universities of Europe had contributed to the renovation of science. The fact is otherwise;—they were often the fastnesses from which prejudice and error were latest of being expelled. They joined in persecuting the reformers of science. It has been seen, that the masters of the university of Paris were angry with Galileo for the experiments on the descent of bodies. Even the university of Oxford brought on itself the indelible disgrace of persecuting, in Friar Bacon, the first man who appears to have had a distinct view of the means by which the knowledge of the laws of nature must be acquired.

which produced it to the writings of the philosopher just named. These examples, and a feeling that the union and co-operation of numbers was necessary to the progress of experimental philosophy, operated still more extensively. The Royal Academy of Sciences at Paris was founded in 1666, in the reign of Louis the Fourteenth, and during the administration of Colbert. The Institute of Bologna in Italy belongs nearly to the same period ; but almost all the other philosophical associations, of which there are now so many, had their beginning in the eighteenth century.

Frequent communication of ideas, and a regular method of keeping up such communication, are evidently essential to works in which great labour and industry are to be employed, and to which much time must necessarily be devoted ; when the philosopher must not always sit quietly in his cabinet, but must examine nature with his own eyes, and be present in the work-shop of the mechanic, or the laboratory of the chemist. These operations are facilitated by the institutions now referred to, which, therefore, are of more importance to the physical sciences than to the other branches of knowledge. They who cultivate the former are also fewer in number, and being, of course, farther separated, are less apt to meet together in the common intercourse of the world. The historian, the critic, the poet, finds everywhere men who can enter in some degree at least into his pursuits, who can appreciate his merit, and derive pleasure from his writings or his conversation. The mathematician, the astronomer, the mechanician, sees few men who have much sympathy with his pursuits, or who do not look with indifference on the objects which he pursues. The *world*, to him, consists of a few individuals, by the censures or approbation of whom the public opinion must be finally determined ; with them it is material that he should have more frequent intercourse than could be obtained by casual rencounter ; and he feels that the society of men engaged in pursuits similar to his own, is a necessary *stimulus* to his exertions. Add to this, that such societies become centers in which information concerning facts is collected from all quarters. For all these reasons, the greatest benefit has resulted from the scientific institutions which, since the middle of the seventeenth century, have become so numerous in Europe.

The Royal Society of London is an association of men, who, without salaries or appointment from Government, defray, by private contribution, the expence of their meetings, and of their publications. This last is another important service, which a society so constituted renders to science.

The demand of the public for memoirs in mathematics and natural philosophy, many of them perhaps profound and difficult, is not sufficiently great to defray the expence of pub-

lication, if they come forward separately and unconnected with one another. In a collective state they are much more likely to draw the attention of the public; the form in which they appear is the most convenient both for the reader and the author; and if, after all, the sale of the work is unequal to the expence, the deficiency is made up from the funds of the society. An institution of this kind, therefore, is a patriotic and disinterested association of the lovers of science, who engage not only to employ themselves in discovery, but, by private contribution, to defray the expence of scientific publications.

The Academy of Sciences in Paris was not exactly an institution of the same kind. It consisted of three classes of members, one of which, the *Pensionnaires*, twenty in number, had salaries paid by Government, and were bound in their turns to furnish the meetings with scientific memoirs, and each of them also, at the beginning of every year, was expected to give an account of the work in which he was to be employed. This institution has been of incredible advantage to science. To detach a number of ingenious men from every thing but scientific pursuits; to deliver them alike from the embarrassments of poverty or the temptations of wealth; to give them a place and station in society the most respectable and independent, is to remove every impediment, and to add every stimulus to exertion. To this institution, accordingly, operating upon a people of great genius, and indefatigable activity of mind, we are to ascribe that superiority in the mathematical sciences, which, for the last seventy years, has been so conspicuous.

The establishment of astronomical observatories, as national or royal works, is connected in Europe with the institution of scientific or philosophical societies. The necessity of the former was, indeed, even more apparent than that of the latter. A science, which has the heavenly bodies for its objects, ought, as far as possible, to be exempted from the vicissitudes of the earth. As it gains strength but slowly, and requires ages to complete its discoveries, the plan of observation must not be limited by the life of the individual who pursues it, but must be followed out in the same place, year after year, to an unlimited extent. A perception of this truth, however indistinct, seems, from the earliest times, to have suggested the utility of observatories, to those sovereigns who patronised astronomy, whether they looked to that science for real or imaginary instruction. The circle of Osymandias is the subject of one of the most ancient traditions in science, and has preserved the name of a prince which otherwise would have been entirely unknown. A building, dedicated to astronomy, made a conspicuous part of the magnificent establishment of the school of Alexandria. During the middle ages, in the course of the migrations of science toward the east, sumptuous buildings, furnished with astronomical instruments, rose successively in the plains of Me-

sopotamia, and among the mountains of Tartary. An observatory in the gardens of the Caliph of Bagdat contained a quadrant of fifteen cubits[1] in radius, and a sextant of forty.[2] Instruments of a still larger size distinguished the observatory of Samarcande, and the accounts would seem incredible, if the ruins of Benares did not, at this moment, attest the reality of similar constructions.

On the revival of letters in Europe, establishments of the same kind were the first decisive indications of a taste for science. We have seen the magnificent observatory on which Tycho expended his private fortune, and employed the munificence of his patron, become a sad memorial (after the signal services which it had rendered to astronomy) of the instability of whatever depends on individual greatness. The observatories at Paris and London were secured from a similar fate, by being made national establishments, where a succession of astronomers were to devote themselves to the study of the heavens. The observatory at Paris was begun in 1667, and that at Greenwich in 1675. In the first of these, La Hire and Cassini, in the second, Flamstead and Halley, are at the head of a series of successors, who have done honour to their respective nations. If there be in Britain any establishment, in the success and conduct of which the nation has reason to boast, it is that of the Royal Observatory, which, in spite of a climate which so continually tries the patience, and so often disappoints the hopes of the astronomer, has furnished a greater number of observations to be completely relied on, than all the rest of Europe put together, and afforded the *data* for those tables, in which the French mathematicians have expressed, with such accuracy, the past, the present, and the future condition of the heavens.

6. Figure and Magnitude of the Earth.

The progress made during the seventeenth century, in ascertaining the magnitude and figure of the earth, is particularly connected with the establishments which we have just been considering. Concerning the figure of the earth, no accurate information was derived from antiquity, if we except that of the mathematical principle on which it was to be determined. The measurement of an arch of the meridian was attempted by Eratosthenes of Alexandria, in perfect conformity with that principle, but by means very inadequate to the importance and difficulty of the problem. By measuring the sun's distance from the zenith of Alexandria, on the solstitial day, and by knowing, as he thought

[1] Twenty-two feet three inches. [2] Sixty feet five inches.

he did, that, on the same day, the sun was exactly in the zenith of Syené, he found the distance in the heavens between the parallels of those places to be 7° 12′, or a 50th part of the circumference of a great circle. Supposing, then, that Alexandria and Syené were in the same meridian, nothing more was required than to find the distance between them, which, when multiplied by 50, would give the circumference of the globe. The manner in which this was attempted by Eratosthenes is quite characteristic of the infant state of the arts of experiment and observation. He took no trouble to ascertain whether Alexandria and Syené were due north and south of one another: the truth is, that the latter is considerably east of the former, so that, though their horizontal distance had been accurately known, a considerable reduction would have been necessary, on account of the distance of the one from the meridian of the other. It does not appear, however, that Eratosthenes was at any more pains to ascertain the distance than the bearing of the two places. He assumed the former just as it was commonly estimated; and, indeed, it appears that the distance was not measured till long afterwards, when it was done by the command of Nero.

It was in this way that the ancients made observations and experiments; the mathematical principles might be perfectly understood, but the method of obtaining accurate data for the application of those principles was not a subject of attention. The *power* of resolving the problem was the main object; and the actual solution was a matter of very inferior importance. The slowness with which the art of making accurate experiments and observations has been matured, and the great distance it has kept behind theory, is a remarkable fact in the history of the physical sciences. It has been remarked, that mathematicians had found out the area of the circle, and calculated its circumference to more than a hundred places of decimals, before artists had divided an arch into minutes of a degree; and that many excellent treatises had been written on the properties of curves, before a straight line had been drawn of any considerable length, or measured with any tolerable exactness, on the surface of the globe.[1]

The next measurement on record is that of the astronomers of Almamon, in the plains of Mesopotamia, and the manner of conducting the operation appears to have been far more accurate than that of the Greek philosophers; but, from a want of knowledge of the *measures* employed, it has conveyed no information to posterity.

---

[1] Edinburgh Review, Vol. V. p. 391.

The first arch of the meridian measured in modern times with an accuracy any way corresponding to the difficulty of the problem, was by Snellius, a Dutch mathematician, who has given an account of it in a volume which he calls *Eratosthenes Batavus*, published in 1617. The arch was between Bergen-op-zoom and Alkmaar; its amplitude was 1° 11′ 30″, and the distance was determined by a series of triangles, depending on a base line carefully measured. The length of the degree that resulted was 55,021 toises, which, as was afterwards found, is considerably too small. Certain errors were discovered, and when they were corrected, the degree came out 57,033 toises, which is not far from the truth. The corrections were made by Snellius himself, who measured his base over again, and also the angles of the triangles. He died, however, before he could publish the result. Muschenbroek, who calculated the whole anew from his papers, came to the conclusion just mentioned, which, of course, was not known till long after the time when the measure was executed. No advantage, accordingly, was derived to the world from this measurement till its value was lost in that of other measurements still more accurately conducted.

A computation which, for the time, deserves considerable praise, is that of Norwood, in 1635, who measured the distance between London and York, taking the bearings as he proceeded along the road, and reducing all to the direction of the meridian, and to the horizontal plane. The difference of latitude he found, by observation of the solstices, to be 2° 28′, and from that and his measured distance, he concluded the degree to be 367,176 feet English, or 57,800 toises. This has been found to be a near approximation; yet his method was not capable of great accuracy, nor did he always execute it in the best manner. "Sometimes," says he, "I measured, sometimes I *paced*, and I believe I am within a *scantling* of the truth."

Fernel, a French physician, measured with a wheel from Paris to Amiens, which are nearly in the same meridian, and he determined the degree from thence to be 56,746 French toises; a result which falls short of the truth, though not very considerably.

These investigations, it is plain, could not but leave considerable uncertainty with respect to the magnitude of the earth. The Academy of Sciences became interested in the question, and the measurement of an arch in the meridian was undertaken under its auspices, and executed by the Abbé Picard, already known for his skill in the operations of practical geometry. He followed a method similar to that of Snellius, according to which, the distance between Amiens and Malvoisine was found from a series of triangles, and a base of 5663$\frac{1}{6}$ toises. He determined the difference of latitude by means of a zenith sector of ten feet radius, and found it to be 1° 22′ 55″. The whole distance was 78,850 toises,

whence the degree came out 57,060 toises. This was the first measurement of a degree of the meridian, on which perfect reliance could be placed.

Hitherto no doubt had been entertained of the spherical figure of the earth, and, of consequence, of the equality of all the degrees of the meridian, so that if one was known, the whole circumference was determined. Men, with the precipitation which they so often manifest, of assuming, without sufficient evidence, the conclusion which appears most simple, were no sooner satisfied that the earth was round, than they supposed it to be truly spherical. An observation soon occurred, which gave reason to suspect, that much more must be done before its figure or its magnitude were completely ascertained.

With a view of observing the sun's altitude in the vicinity of the equator, where the distance from the zenith being inconsiderable, the effects of refraction must be of small account, it was agreed, by the same academy, to send an astronomer, M. Richer, to make observations at the island of Cayenne, in South America.

Richer observed the solstitial altitude of the sun at that place in 1672, and found the distance of the tropics to be 46° 57′ 4″; and, therefore, the obliquity of the ecliptic 23° 28′ 32″, agreeing almost precisely with the determination of Cassini.

The most remarkable circumstance, however, which occurred in the course of this voyage, was, that the clock, though furnished with a pendulum of the same length which vibrated seconds at Paris, was found, at Cayenne, to lose two minutes and a half a-day nearly. This created great astonishment in France, especially after the accuracy of it was confirmed by the observations of Varin and Deshayes, who, some years afterwards, visited different places on the coast of Africa and America, near the line, and found the necessity of shortening the pendulum, to make it vibrate seconds in those latitudes. The first explanation of this remarkable phenomenon was given by Newton, in the third book of his *Principia*, published in 1687, where it is deduced as a necessary consequence of the earth's rotation on its axis, and of the centrifugal force thence arising. That force changes both the direction and the intensity of gravity, giving to the earth an oblate spheroidal figure, more elevated at the equator than the poles, and making bodies fall, and pendulums vibrate, more slowly in low than in high latitudes.

This solution, however, did not, any more than the book in which it was contained, make its way very readily into France. The first explanation of the retardation of the pendulum, which was received there, was given by Huygens in 1690. Huygens deduced it also from the centrifugal force, arising from the earth's rotation, and the view which he took was simpler, though much less accurate than that of Newton. It had, indeed, the simplicity which often arises from neglecting one of the essential conditions of a problem;

but it was nevertheless ingenious, and involved a very accurate knowledge of the nature of centrifugal force. I am thus brought to touch on a subject which belongs properly to the second part of this Dissertation, for which the fuller discussion of it must of course be reserved.

SECTION V.

OPTICS.

1. OPTICAL KNOWLEDGE OF THE ANCIENTS.

ON account of the rectilineal propagation of light, the phenomena of optics are easily expressed in the form of mathematical propositions, and seem, as it were, spontaneously to offer themselves to the study of geometers. Euclid perceiving this affinity, began to apply the science which he had already cultivated with so much success, to explain the laws of vision, before a similar attempt had been made with respect to any other branch of terrestrial physics, and at least fifty years before the researches of Archimedes had placed mechanics among the number of the mathematical sciences.

In the treatise ascribed to Euclid, there are, however, only two physical principles which have completely stood the test of subsequent improvement. The first of these is the proposition just referred to, that a point in any object is seen in the direction of a straight line drawn from the eye to that point; and the second is, that when a point in an object is seen by reflection from a polished surface, the lines drawn from the eye and from the object to the point whence the reflection is made, are equally inclined to the reflecting surface. These propositions are assumed as true; they were, no doubt, known before the time of Euclid, and it is supposed that the discovery of them was the work of the Platonic school. The first of them is the foundation of Optics *proper*, or the theory of vision by direct light; the second is the foundation of *Catoptrics*, or the theory of vision by reflected light. Dioptrics, or vision by refracted light, had not yet become an object of attention.

Two other principles which Euclid adopted as postulates in his demonstrations, have not met with the same entire confirmation from experiment, and are, indeed, true only in certain cases, and not universally, as he supposed. The first of these is, that we judge of the magnitude of an object altogether by the magnitude of the optical angle, or the angle which it subtends at the eye. It is true that this angle is an important ele-

ment in that judgment, and Euclid, by discovering this, came into the possession of a valuable truth ; but by a species of sophistry, very congenial to the human mind, he extended the principle too far, and supposed it to be the only circumstance which determines our judgment of visible magnitude. It is, indeed, the only measure which we are furnished with directly by the eye itself; but there are few cases in which we form our estimate without first appealing to the commentary afforded by the sensations of touch, or the corrections derived from our own motion.

Another principle, laid down by the same geometer, is in circumstances nearly similar to the preceding. According to it, the place of any point of an object seen by reflection, is always the intersection of the reflected ray, with the perpendicular drawn from that point to the reflecting surface. The proof offered is obscure and defective ; the proposition, however, is true, of plain speculums always, and of spherical as far as Euclid's investigations extended, that is, while the rays fall on the speculum with no great obliquity. His assumption, therefore, did not affect the truth of his conclusions, though it would have been a very unsafe guide in more general investigations. The book is in many other respects imperfect, the reasoning often unsound, and the whole hardly worthy of the great geometer whose name it bears. There is, however, no doubt that Euclid wrote on the subject of optics, and many have supposed that this treatise is a careless extract, or an unskilful abridgment of the original work.

Antiquity furnished another mathematical treatise on optics, that of the astronomer Ptolemy. This treatise, though known in the middle ages, and quoted by Roger Bacon, had disappeared, and was supposed to be entirely lost, till within these few years, when a manuscript on optics, professing to be the work of Ptolemy, and to be translated from the Arabic, was found in the King's Library at Paris. The most valuable part of this work is that which relates to refraction, from whence it appears that many experiments had been made on that subject, and the angles of incidence and refraction, for different transparent substances, observed with so much accuracy, that the same ratio very nearly of the sines of these angles, from air into water, or into glass, is obtained from Ptolemy's numbers, which the repeated experiments of later times have shown to be true. The work, however, in the state in which it now appears, is very obscure, the reasoning often deficient in accuracy, and the mathematical part much less perfect than might have been expected. Modern writers, presuming partly on the reputation of Ptolemy, and partly guided by the authority of Roger Bacon, had ascribed to this treatise more merit than it appears to possess; and, of consequence, had allowed less to the Arabian author Alhazen, who comes next in the order of time, than of right belongs to him. Montucla, on the

authority of Bacon, says, that Ptolemy ascribed the increase of the apparent magnitude of the heavenly bodies near the horizon, to the greater distance at which they are supposed to be, on account of the number of intervening objects across which they are seen. Ptolemy's explanation, however, as stated by Delambre, [1] from the manuscript just mentioned, is quite different from this, and amounts to no more than the vague and unsatisfactory remark, that an observer looks at the bodies near the zenith in a constrained posture, and in a situation to which the eye is not accustomed. The former explanation, therefore, given by Alhazen, but supposed to have been borrowed from Ptolemy, must now be returned to its right owner. It is the best explanation yet known.

These are the only mathematical treatises on optics of any consideration which the ancients have transmitted to us; [2] but many metaphysical speculations on light and vision are to be found in the writings of the philosophers. Aristotle defined light much as he had defined motion; *the act or energy of a transparent body, in as much as it is transparent.* The reason for calling light an act of a transparent body is, that, though a body may be transparent in power or capacity, it does not become actually transparent but by means of light. Light brings the transparency into action; it is, therefore, the act of a transparent body. In such miserable puerilities did the genius of this great man exhaust itself, owing to the unfortunate direction in which his researches were carried on.

In his farther speculations concerning light, he denied it to be a substance; and his argument contains a singular mixture of the ingenious and the absurd. The time, he says, in which light spreads from one place to another is infinitely small, so that light has a velocity which is infinitely great. Now, bodies move with a velocity inversely as the quantities of matter which they contain; light, therefore, cannot contain any mat-

---

[1] *Connaissance des Tems,* 1816, p. 245, &c. The glimpses of truth, not destined to be fully discovered till many ages afterwards, which are found in the writings of the ancients, are always interesting. Ptolemy distinguishes what has since been called the *virtual focus,* which takes place in certain cases of reflection from spherical specula. He remarks, that colours are confounded by the rapidity of motion, and gives the instance of a wheel painted with different colours, and turned quickly round.

[2] Another Greek treatise on optics, that of *Heliodorus of Larissa,* has been preserved, and was first published by Erasmus Bartholinus at Paris, in 1657. It is a superficial work, which, to a good deal of obscure and unsound metaphysics, adds the demonstration of a few very obvious truths. The author holds the opinion, that vision is performed by the emission of something from the eyes; and the reason which he assigns is, that the eyes are convex, and more adapted to emit than to receive. His metaphysics may be judged of from this specimen. He has not been made mention of by any ancient author, and the time when he wrote is unknown. As he quotes, however, the writings of Ptolemy and Hero, he must have been later than the first century.

ter, that is, it cannot be material.[1] That the velocity of light was infinitely great, seemed to him to follow from this, that its progress, estimated either in the direction of north and south, or of east and west, appeared to be instantaneous. In the opinion of the Platonists, and of the greater part of the ancients, vision was performed by means of certain rays which proceeded from the eye to the object, though they did not become the instruments of conveying sensations to the mind, but in consequence of the presence of light. In this theory, we can now see nothing but a rude and hasty attempt to assimilate the sense of sight to that of touch, without inquiring sufficiently into the particular characters of either.

Epicurus, and the philosophers of his school, as we learn from Lucretius, entertained more correct notions of vision, though they were still far from the truth. They conceived vision to be performed in consequence of certain *simulacra*, or images continually thrown off from the surfaces of bodies, and entering the eye. This was the substitute in their philosophy for rays of light, and had at least the merit of representing that which is the medium of vision, or which forms the communication between the eye and external objects, as something proceeding from the latter. The idea of *simulacra*, or *spectra*, flying off continually from the surfaces of bodies, and entering the eye, was perhaps as near an approach to the true theory of vision as could be made before the structure of the eye was understood.

In the arts connected with optics, the ancients had made some progress. They were sufficiently acquainted with the laws of reflection to construct mirrors both plane and spherical. They made them also conical; and it appears from Plutarch, that the fire of Vesta, when extinguished, was not permitted to be rekindled but by the rays of the sun, which were condensed by a conical speculum of copper. The mirrors with which Archimedes set fire to the Roman gallies have been subjects of much discussion, and the fact was long disbelieved, on the ground of being physically impossible. The experiments of Kircher and Buffon showed that this impossibility was entirely imaginary, and that the effect ascribed to the *specula* of the Greek geometer might be produced without much difficulty. There remains now no doubt of their reality. A passage from Aristophanes[2] gives reason to believe that, in his time, lenses of glass were used for burning, by col-

---

[1] The truth of the mathematical proposition, that $\frac{1}{\text{inf.}} = 0$, was perceived by Aristotle. A strong intellect is always visible in the midst of his greatest errors.

[2] In Nubibus, Act. 2. sc. 1. v. 20.

lecting the rays of the sun; but in a matter that concerns the history of science, the authority of a comic poet and a satirist would not deserve much attention, if it were not confirmed by more sober testimony. Pliny, speaking of rock crystal,[1] says that a globe or ball of that substance was sometimes used by the physicians for collecting the rays of the sun, in order to perform the operation of cautery. In another passage, he mentions the power of a glass globe filled with water, to produce a strong heat when exposed to the rays of the sun, and expresses his surprise that the water itself should all the while remain quite cold.

With respect to the power of glasses to magnify objects seen through them, or to render such objects more distinct, the ancients appear to have observed ill, and to have reasoned worse. "Literæ quamvis minutæ et obscuræ per vitream pilam aqua plenam majores clarioresque cernuntur. Sidera ampliora per nubem adspicienti videntur: *quia acies nostra in humido labitur, nec apprehendere quod vult fideliter potest.*"[2] This passage, and the speculations concerning the rainbow in the same place, when they are considered as containing the opinions of some of the most able and best informed men of antiquity, must be admitted to mark, in a very striking manner, the infancy of the physical sciences.

2. From Alhazen to Kepler.

An interval of nearly a thousand years divided Ptolemy from Alhazen, who, in the history of optical discovery, appears as his immediate successor. This ingenious Arabian lived in the eleventh century, and his merit can be more fairly, and will be more highly appreciated, now that the work of his predecessor has become known. The merit of his book on Optics was always admitted, but he was supposed to have borrowed much from Ptolemy, without acknowledging it; and the prejudices entertained in favour of a Greek author, especially of one who had been for so many years a legislator in science, gave a false impression, both of the genius and the integrity of his modern rival. The work of Alhazen is, nevertheless, in many respects, superior to that of Ptolemy, and in nothing more than in the geometry which it employs. The problem known by his name, to find the point in a spherical speculum, at which a ray coming from one given point shall be reflected to another given point, is very well resolved in his book, though a problem of so much difficulty, that Montucla hazards

[1] Hist. Nat. Lib. 37. cap. 10.

[2] Seneca, Nat. Quest. Lib. i. cap. 6.

the opinion, that no Arabian geometer was ever equal to the solution of it.[1] It is now certain, however, that the solution, from whatever quarter it came, was not borrowed from Ptolemy, in whose work no mention is made of any such question; and it may very well be doubted, whether, had this problem been proposed to him, the Greek geometer would have appeared to as much advantage as the Arabian.

The account which the latter gives of the augmentation of the diameters of the heavenly bodies near the horizon has been already mentioned. He treated also of the refraction of light by transparent bodies, and particularly of the atmospheric refraction, but not with the precision of Ptolemy, whose optical treatise Delambre seems to think it probable that he had never seen. The anatomical structure of the eye was known to him; concerning the uses of the different parts he had only conjectures to offer; but on seeing single with two eyes, he made this very important remark, that, when corresponding parts of the retina are affected, we perceive but one image.

Prolixity and want of method are the faults of Alhazen. Vitello,[2] a learned Pole, commented on his works, and has very much improved their method and arrangement in a treatise published in 1270. He has also treated more fully of the subject of refraction, and reduced the results of his experiments into the form of a table exhibiting the angles of refraction corresponding to the angles of incidence, which he had tried in water and glass. It was not, however, till long after this period that the law which connects these angles was discovered. The cause of refraction appeared to him to be the resistance which the rays suffer in passing into the denser medium of water or glass, and one can see in his reasoning an obscure idea of the resolution of forces. He also treats of the rainbow, and remarks, that the altitudes of the sun and bow together always amount to 42 degrees. He next considers the structure of the eye, of which he has given a tolerably accurate description, and proves, as Alhazen had before done,[3] that vision is not performed by the emission of rays from the eye.

Roger Bacon, distinguished for pursuing the path of true philosophy in the midst of an

---

[1] Barrow, in his 9th lecture, says of this Problem, that it may truly be called δυσμήχανον, as hardly any one more difficult had then been attempted by geometers. He adds, that, after trying the analysis in many different ways, he had found nothing preferable to the solution of Alhazen, which he therefore gives only freed from the prolixness and obscurity with which the original is chargeable. *Lectiones Opticæ*, *Sect.* 9. p. 65. A very elegant solution of the same problem is given by Simson, at the end of his Conic Sections.

[2] The name of this author is commonly written *Vitellio*. He may be supposed to have known best the orthography of his own name.

[3] Alhazen, Opt. lib. 1.

age of ignorance and error, belongs to the same period; and applied to the study of optics with peculiar diligence. It does not appear, however, that he added much to the discoveries of Alhazen and Ptolemy, with whose writings, particularly those of the former, he seems to have been well acquainted. In some things he was much behind the Arabian optician, as he supposed with the ancients that vision is performed by rays emitted from the eye. It must, however, be allowed, that the arguments employed on both sides of this question are so weak and inconclusive, as very much to diminish the merit of being right, and the demerit of being wrong. What is most to the credit of Bacon, is the near approach he appears to have made to the knowledge of lenses, and their use in assisting vision. Alhazen had remarked, that small objects, letters, for instance, viewed through a segment of a glass sphere, were seen magnified, and that it is the larger segment which magnifies the most. The spherical segment was supposed to be laid with its base on the letters, or other minute objects which were to be viewed. Bacon recommends the smaller segment, and observes, that the greater, though it magnify more, places the object farther off than its natural position, while the other brings it nearer. This shows sufficiently, that he knew how to trace the progress of the rays of light through a spherical transparent body, and understood, what was the thing least obvious, how to determine the place of the image. Smith, in his Optics, endeavours to show, that these conclusions were purely theoretical, and that Roger Bacon had never made any experiments with such glasses, notwithstanding that he speaks as if he had done so.[1] This severe remark proceeds on some slight inaccuracy in Bacon's description, which, however, does not seem sufficient to authorize so harsh a conclusion. The probability appears rather to be, as Molineux supposed, that Bacon had made experiments with such glasses, and was both practically and theoretically acquainted with their properties. At the same time, it must be acknowledged, that his credulity on many points, and his fondness for the marvellous, which, with every respect for his talents, it is impossible to deny, take something away from the force of his testimony, except when it is very expressly given. However that may be in the present case, it is probable, that the knowledge of the true properties of these glasses, whether it was theoretical or practical, may have had a share in introducing the use of lenses, and in the invention of spectacles, which took place not long after.

It would be desirable to ascertain the exact period of an invention of such singular uti-

---

[1] Smith's Optics, Vol. II. Remarks, § 76.

lity as this last; one that diffuses its advantages so widely, and that contributes so much to the solace and comfort of old age, by protecting the most intellectual of the senses against the general progress of decay. In the obscurity of a dark age, careless about recording discoveries of which it knew not the principle or the value, a few faint traces and imperfect indications serve only to point out certain limits within which the thing sought for is contained. Seeking for the origin of a discovery, is like seeking for the source of a river where innumerable streams have claims to the honour, between which it is impossible to decide, and where the only thing that can be known with certainty is the boundary by which they are all circumscribed. The reader will find the evidence concerning the invention of spectacles very fully discussed in Smith's *Optics*, from which the most probable conclusion is, that the date goes back to the year 1313, and cannot with any certainty be traced farther.[1]

The lapse of more than two hundred years brings us down to Maurolycus, and to an age when men of science ceased to be so thinly scattered over the wastes of time. Maurolycus, whose knowledge of the pure mathematics has been already mentioned, was distinguished for his skill in optics. He was acquainted with the crystalline lens, and conceived that its office is to transmit to the optic nerve the *species* of external objects; and in this process he does not consider the retina as any way concerned. This theory, though so imperfect, led him nevertheless to form a right judgment of the defects of short-sighted and long-sighted eyes. In one of his first works, *Theoremata de Lumine et Umbra*, he also gives an accurate solution of a question proposed by Aristotle, viz. why the light of the sun, admitted through a small hole, and received on a plane at a certain distance from it, always illuminates a round space, whatever be the figure of the hole itself, whereas, through a large aperture, the illuminated space has the figure of the aperture. To conceive the reason of this, suppose that the figure of the hole is a triangle; it is plain that at each angle the illuminated space will be terminated by a circular arch of which the centre corresponds to the angular point, and the radius to the angle subtended by the sun's semidiameter. Thus the illuminated space is rounded off at the angles; and when the hole is so small that the size of those roundings bears a large proportion to the distance of their centres, the figure comes near to a circle, and may be to appearance quite round. This is the true solution, and the same with that of Mauro-

---

[1] Smith's Optics, Vol. II. Remarks, § 75.

lycus. The same author appears also to have observed the caustic curve formed by reflection from a concave speculum.

A considerable step in optical discovery was made at this time by Baptista Porta, a Neapolitan, who invented the *Camera Obscura*, about the year 1560, and described it in a work, entitled *Magia Naturalis*. The light was admitted through a small hole in the window-shutter of a dark room, and gave an inverted picture of the objects from which it proceeded, on the opposite wall. A lens was not employed in the first construction of this apparatus, but was afterwards used; and Porta went so far as to consider how the effect might be produced without inversion. He appears to have been a man of great ingenuity; and though much of the *Magia Naturalis* is directed to frivolous objects, it indicates a great familiarity with experiment and observation. It is remarkable, that we find mention made in it of the reflection of cold by a speculum,[1] an experiment which, of late, has drawn so much attention, and has been supposed to be so entirely new. The cold was perceived by making the focus fall on the eye, which, in the absence of the thermometer, was perhaps the best measure of small variations of temperature. Porta's book was extremely popular; and when we find it quickly translated into Italian, French, Spanish, and Arabic, we see how much the love of science was now excited, and what effects the art of printing was now beginning to produce. Baptista Porta was a man of fortune, and his house was so much the resort of the curious and learned at Naples, that it awakened the jealousy with which the court of Rome watched the progress of improvement. How grievous it is to observe the head of the Christian church in that and the succeeding age, like the *Anarch old* in Milton, reigning in the midst of darkness, and complaining of the encroachments which the realm of light was continually making on his ancient empire!

The constitution of the eye, and the functions of the different parts of which it consists, were not yet fully understood. Maurolycus had nearly discovered the secret, and it was but a thin, though, to him, an impenetrable veil, which still concealed one important part of the truth. This veil was drawn aside by the Neapolitan philosopher; but the complete discovery of the truth was left to Kepler, who, to the glory of finding out the true laws of the planetary system, added that of first analyzing the whole scheme of nature in the structure of the eye. He perceived the exact resemblance of this organ to the *dark chamber*, the rays entering the pupil being collected by the crystalline lens, and the other hu-

[1] Magia Naturalis, Lib. 17. cap. 4. p. 583. Amsterdam edit. 1664.

mours of the eye, into *foci*, which paint on the *retina* the inverted images of external objects. By another step of the process, to which our analysis can never be expected to extend, the mind perceives the images thus formed, and refers them at the same time to things without.

It seemed a great difficulty, that, though the images be inverted, the objects are seen erect; but when it is considered that each point in the object is seen in the direction of the line in which the light passes from it to the retina, through the centre of the eye, it will appear that the upright position of the object is a necessary consequence of this arrangement.

Kepler's discovery is explained in his *Paralipomena in Vitellionem*[1] (Remarks on the Optics of Vitello), a work of great genius, abounding with new and enlarged views, though mixed occasionally with some unsound and visionary speculations. This book appeared in 1604. In the next article we shall have occasion to return to the consideration of other parts of Kepler's optical discoveries.

3. From Kepler to the commencement of Newton's Optical Discoveries.

The rainbow had, from the earliest times, been an object of interest with those who bestowed attention on optical appearances, but it is much too complicated a phenomenon to be easily explained. In general, however, it was understood to arise from light reflected by the drops of rain falling from a cloud opposite to the sun. The difficulty seemed to be how to account for the colour, which is never produced in white light, such as that of the sun, by mere reflection. Maurolycus advanced a considerable step when he supposed that the light enters the drop, and acquires colour by refraction; but in tracing the course of the ray he was quite bewildered. Others supposed the refraction and the colour to be the effect of one drop, and the reflection of another; so that two refractions and one reflection were employed, but in such a manner as to be still very remote from the truth.

Antonio de Dominis, Archbishop of Spalatro, had the good fortune to fall upon the true explanation. Having placed a bottle of water opposite to the sun, and a little above his eye, he saw a beam of light issue from the under side of the bottle, which acquired different colours, in the same order, and with the same brilliancy as in the rainbow, when the bottle was a little raised or depressed. From comparing all the circumstances, he perceived that the rays had entered the bottle, and that, after two refractions from the convex part, and

[1] Caput 5. de Modo Visionis.

a reflection from the concave, they were returned to the eye tinged with different colours, according to the angle at which the ray had entered. The rays that gave the same colour made the same angle with the surface, and hence all the drops that gave the same colour must be arranged in a circle, the centre of which was the point in the cloud opposite to the sun. This, though not a complete theory of the rainbow, and though it left a great deal to occupy the attention, first of Descartes, and afterwards of Newton, was perfectly just, and carried the explanation as far as the principles then understood allowed it to go. The discovery itself may be considered as an anomaly in science, as it is one of a very refined and subtle nature, made by a man who has given no other indication of much scientific sagacity or acuteness. In many things his writings show great ignorance of principles of optics well known in his own time, so that Boscovich, an excellent judge in such matters, has said of him, " homo opticarum rerum, supra id quod patiatur ea ætas imperitissimus." The book containing this discovery was published in 1611.[1]

A discovery of the same period, but somewhat earlier, will always be considered as among the most remarkable in the whole circle of human knowledge. It is the invention of the telescope, the work in which (by following unconsciously the plan of nature in the formation of the eye) man has come the nearest to the construction of a new organ of sense. For this great invention, in its original form, we are indebted to accident, or to the trials of men who had little knowledge of the principles of the science on which they were conferring so great a favour. A series of scientific improvements, continued for more than two hundred years, has continually added to the perfection of this noble instrument, and has almost entitled science to consider the telescope as its own production.

It will readily be believed, that the origin of such an invention has been abundantly inquired into. The result, however, as is usual in such cases, has not been quite satisfactory; and all that is known with certainty is, that the honour belongs to the town of Middleburgh in Zealand, and that the date is between the last ten years of the sixteenth century, and the first ten of the seventeenth. Two different workmen belonging to that town, Zachariah Jans, and John Lapprey, have testimonies in their favour between which it is difficult to decide; the former goes back to 1590, the latter comes down to about 1610. It is not of much consequence to settle the priority in a matter which is purely accidental; yet one would not wish to forget or mistake the names of men whom even

[1] De Radiis Lucis in Vitris perspectivis et Iride.—Venetiis, in 4to.

chance had rendered so great benefactors to science. What we know with certainty is, that the account of the effect produced by this new combination of glasses being carried to Galileo in 1610, led that great philosopher to the construction of the telescope, and to the interesting discoveries already enumerated. By what principle he was guided to the combination, which consists of one convex and one concave lens, he has not explained, and we cannot now exactly ascertain. He had no doubt observed, that a convex lens, such as was common in spectacles, formed images of objects, which were distinctly seen when thrown on a wall or on a screen. He might observe also, that if the image, instead of falling on the screen, were made to fall on the eye, the vision was confused and indistinct. In the trials to remedy this indistinctness, by means of another glass, it would be found that a concave lens succeeded when placed before the eye, the eye itself being also a little more advanced than the screen had been.

This instrument, though very imperfect, compared with those which have been since constructed, gave so much satisfaction, that it remained long without any material improvement. Descartes, whose treatise on Optics was written near thirty years after the invention of the telescope, makes no mention of any but such as is composed of a convex object-glass, and a concave eye-glass. The theory of it, indeed, was given by Kepler in his Dioptrics (1611), when he also pointed out the astronomical telescope, or that which is composed of two convex lenses, and inverts the objects. He did not, however, construct a telescope of that kind, which appears to have been first done by *Scheiner*, who has given an account of it in the *Rosa Ursina* (in 1650), quoted by Montucla.[1]

After the invention of the telescope, that of the microscope was easy; and it is also to Galileo that we are indebted for this instrument, which discovers an immensity on the one side of man, scarcely less wonderful than that which the telescope discovers on the other. The extension and divisibility of matter are thus rendered to the natural philosopher almost as unlimited as the extension and the divisibility of space are to the geometer.

The theory of the telescope, now become the main object in optical science, required that the law of refraction should, if possible, be accurately ascertained. This had not yet been effected, and Kepler, whose *Dioptrics* was the most perfect treatise on refraction which had yet appeared, had been unable to determine the general principle which connects the angles of incidence and refraction. In the case of glass, he had found by experiment, that those angles, when small, are nearly in the ratio of three to two, and on

---

[1] Vol. II. p. 234, 2d edit.

this hypothesis he had found the focus of a double convex lens, when the curvature of both sides is equal, to be the centre of curvature of the side turned toward the object,—a proposition which is known to coincide with experiment. From the same approximation, he derived other conclusions, which were found useful in practice, in the cases where the angles just mentioned were very small.

The discovery of the true law of refraction was the work of Snellius, the same mathematician whose labours concerning the figure of the earth were before mentioned. In order to express this law, he supposed a perpendicular to the refracting surface, at the point where the refraction is made, and also another line parallel to this perpendicular at any given distance from it. The refracted ray, as it proceeds, will meet this parallel, and the incident ray is supposed to be produced, till it do so likewise. Now, the general truth which Snellius found to hold, whatever was the position of the incident ray, is, that the segments of the refracted ray and of the incident ray, intercepted by these parallels, had always the same ratio to one another. If either of the *media* were changed, that through which the incident ray, or that through which the refracted ray passed, this ratio would be changed, but while the *media* remained the same, the ratio continued unalterable. It is seldom that a general truth is seen at first under the most simple aspect: this law admits of being more simply expressed, for, in the triangle formed by the two segments of the rays, and by the parallel which they intersect, the said segments have the same ratio with the sines of the opposite angles, that is, with the sines of the angles of incidence and refraction. The law, therefore, comes to this, that, in the refraction of light, by the same medium, the sine of the angle of incidence has to the sine of the angle of refraction always the same ratio. This last simplification did not occur to Snellius; it is the work of Descartes, and was first given in his *Dioptrics*, in 1637, where no mention is made of Snellius, and the law of refraction appears as the discovery of the author. This naturally gave rise to heavy charges against the candour and integrity of the French philosopher. The work of Snellius had never been published, and the author himself was dead; but the proposition just referred to had been communicated to his friends, and had been taught by his countryman, Professor Hortensius, in his lectures. There is no doubt, therefore, that the discovery was first made by Snellius, but whether Descartes derived it from him, or was himself the second discoverer, remains undecided. The question is one of those, where a man's conduct in a particular situation can only be rightly interpreted from his general character and behaviour. If Descartes had been uniformly fair and candid in his intercourse with others, one would have rejected with disdain a suspicion of the kind just mentioned. But the truth is, that he appears through-

out a jealous and suspicious man, always inclined to depress and conceal the merit of others. In speaking of the inventor of the telescope, he has told minutely all that is due to accident, but has passed carefully over all that proceeded from design, and has incurred the reproach of relating the origin of that instrument, without mentioning the name of Galileo. In the same manner, he omits to speak of the discoveries of Kepler, so nearly connected with his own; and in treating of the rainbow, he has made no mention of Antonio de Dominis. It is impossible that all this should not produce an unfavourable impression, and hence it is, that even the warmest admirers of Descartes do not pretend that his conduct toward Snellius can be completely justified.

Descartes would have conceived his philosophy to be disgraced if it had borrowed any general principle from experience, and he therefore derived, or affected to derive, the law of refraction from reasoning or from theory. In this reasoning, there were so many arbitrary suppositions concerning the nature of light, and the action of transparent bodies, that no confidence can be placed in the conclusions deduced from it. It is indeed quite evident, that, independently of experiment, Descartes himself could have put no trust in it, and it is impossible not to feel how much more it would have been for the credit of that philosopher to have fairly confessed that the knowledge of the law was from experiment, and that the business of theory was to deduce from thence some inferences with respect to the constitution of light and of transparent bodies. This I conceive to be the true method of philosophizing, but it is the reverse of that which Descartes pursued on all occasions.

The weakness of his reasoning was perceived and attacked by Fermat, who, at the same time, was not very fortunate in the theory which he proposed to substitute for that of his rival. The latter had laid it down as certain, that light, of which he supposed the velocity infinite, or the propagation instantaneous, meets with less obstruction in dense than in rare bodies, for which reason, it is refracted toward the perpendicular, in passing from the latter into the former. This seemed to Fermat a very improbable supposition, and he conceived the contrary to be true, viz. that light in rare bodies has less obstruction, and moves with greater velocity than in dense bodies. On this supposition, and appealing, not to physical, but to final causes, Fermat imagined to himself that he could deduce the true law of refraction. He conceived it to be a fact that light moves always between two points, so as to go from the one to the other in the least time possible. Hence, in order to pass from a given point in a rarer medium where it moves faster, to a given point in a denser medium where it moves slower, so that the time may be a *minimum*, it must continue longer in the former medium than if it held a rectilineal course, and the bending of its path, on entering the latter, will

therefore be toward the perpendicular. On instituting the calculus, according to his own doctrine of *maxima* and *minima*, Fermat found, to his surprise, that the path of the ray must be such, that the sines of the angles of incidence and refraction have a constant ratio to one another. Thus did these philosophers, setting out from suppositions entirely contrary, and following routes which only agreed in being quite unphilosophical and arbitrary, arrive, by a very unexpected coincidence, at the same conclusion. Fermat could no longer deny the law of refraction, as laid down by Descartes, but he was less than ever disposed to admit the justness of his reasoning.

Descartes proceeded from this to a problem which, though suggested by optical considerations, was purely geometrical, and in which his researches were completely successful. It was well known, that, in the ordinary cases of refraction by spherical and other surfaces, the rays are not collected into one point, but have their foci spread over a certain surface, the sections of which are the curves called caustic curves, and that the focus of opticians is only a point in this surface, where the rays are more condensed, and, of course, the illumination more intense than in other parts of it. It is plain, however, that if refraction is to be employed, either for the purpose of producing light or heat, it would be a great advantage to have all the rays which come from the same point of an object united accurately, after refraction, in the same point of the image. This gave rise to an inquiry into the figure which the superficies, separating two transparent *media* of different refracting powers, must have, in order that all the rays diverging from a given point might, by refraction at the said superficies, be made to converge to another given point.[1] The problem was resolved by Descartes in its full extent; and he proved, that the curves, proper for generating such superficies by their revolution, are all comprehended under one general character, viz. that there are always two given points, from which, if straight lines be drawn to any point in the curve, the one of these, *plus* or *minus*, that which has a given ratio to the other, is equal to a given line.

It is evident, when the given ratio here mentioned is a ratio of equality, that the curve is a conic section, and the two given points its two foci. The curves, in general, are of the fourth or the second order, and have been distinguished by the name of the ovals of Descartes.

From this very ingenious investigation no practical result of advantage in the construction of lenses has been derived. The mechanical difficulties of working a superficies into any figure but a spherical one are so great, that, notwithstanding all the ef-

---

[1] Cartesii Dioptrices, cap. 8vum; Geometria, lib. 2dus.

forts of Descartes himself, and of many of his followers, they have never been overcome, so that the great improvements in optical instruments have arisen in a quarter entirely different.

Descartes gave also a full explanation of the rainbow,[1] as far as colour was not concerned, a part of the problem which remained for Newton to resolve. The path of the ray was traced, and the angles of the incident ray, with that which emerges after two refractions and one reflection, was accurately determined. Descartes paid little attention to those who had gone before him, and, as already remarked, never once mentioned the Archbishop of Spalatro. Like Aristotle, he seems to have formed the design of cutting off the memory of all his predecessors, but the invention of printing had made this a far more hopeless undertaking than it was in the days of the Greek philosopher.

After the publication of the *Dioptrics* of Descartes, in 1637, a considerable interval took place, during which optics, and indeed science in general, made but little progress, till the *Optica Promota* of James Gregory, in 1663, seemed to put them again in motion. The author of this work, a profound and inventive geometer, had applied diligently to the study of optics and the improvement of optical instruments. The *Optica Promota* embraced several new inquiries concerning the illumination and distinctness of the images formed in the foci of lenses, and contained an account of the Reflecting Telescope still known by the name of its author. The consideration which suggested this instrument was the imperfection of the images formed by spherical lenses, in consequence of which, they are not in plane, but in curved surfaces. The desire of removing this imperfection led Gregory to substitute reflection for refraction in the construction of telescopes; and by this means, while he was seeking to remedy a small evil, he provided the means of avoiding a much greater one, with which he was not yet acquainted, viz. that which arises from the unequal refrangibility of light. The attention of Newton was about the same time drawn to the same object, but with a perfect knowledge of the defect which he wanted to remove. Gregory thought it necessary that the specula should be of a parabolic figure; and the execution proved so difficult, that the instrument, during his own life, was never brought to any perfection. The specula were afterwards constructed of the ordinary spherical form, and the Gregorian telescope, till the time of Dr Herschel, was more in use than the Newtonian.

Gregory was professor of mathematics at St Andrews, and afterwards for a short time at Edinburgh. His writings strongly mark the imperfect intercourse which subsisted at

---

[1] Meteorum, cap. 8vum.

that time between this country and the Continent. Though the *Optics* of Descartes had been published twenty-five years, Gregory had not heard of the discovery of the law of refraction, and had found it out only by his own efforts ;—happy in being able, by the fertility of his genius, to supply the defects of an insulated and remote situation.

A course of lectures on optics, delivered at Cambridge in 1668, by Dr Barrow, and published in the year following, treated of all the more difficult questions which had occurred in that state of the science, with the acuteness and depth which are found in all the writings of that geometer. This work contains some new views in optics, and a great deal of profound mathematical discussion.

About this time Grimaldi, a learned jesuit, the companion of Riccioli, in his astronomical labours, made known some optical phenomena which had hitherto escaped observation. They respected the action of bodies on light, and when compared with reflection and refraction, might be called, in the language of Bacon's philosophy, *crepuscular* instances, indicating an action of the same kind, but much weaker and less perceptible. Having stretched a hair across a sun-beam, admitted through a hole in the window-shutter of a dark chamber, he was surprised to find the shadow much larger than the natural divergence of the rays could have led him to expect. Other facts of the same kind made known the general law of the *diffraction* or *inflexion* of light, and showed that the rays are acted on by bodies, and turned out of their rectilineal course, even when not in contact, but at a measurable distance from the surfaces or edges of such bodies. Grimaldi gave an account of those facts in a treatise printed at Bologna in 1665. [1]

Optics, as indeed all the branches of natural philosophy, have great obligations to Huygens. The former was among the first scientific objects which occupied his mind ; and his *Dioptrics*, though a posthumous work, is most of it the composition of his early youth. It is written with great perspicuity and precision, and is said to have been a favourite book with Newton himself. Though beginning from the first elements, it contains a full developement of the matters of greatest difficulty in the construction of telescopes, particularly in what concerns the indistinctness arising from the imperfect foci into which rays are united by spherical lenses ; and rules are deduced for constructing telescopes, which, though of different sizes, shall have the same degree of distinctness, illumination, &c. Huygens was besides a practical optician ; he polished lenses, and constructed telescopes with his own hands, and some of his object-glasses were of the enormous focal distance of 130 feet. To his *Dioptrics* is added a valuable treatise *De Formandis Vitris*.

[1] Physico-Mathesis de Lumine, Coloribus, &c. in 4to.

In the history of optics, particular attention is due to his theory of light, which was first communicated to the Academy of Sciences of Paris, in 1678, and afterwards published, with enlargements, in 1690.[1]

Light, according to this ingenious system, consists in certain undulations communicated by luminous bodies to the etherial fluid which fills all space. This fluid is composed of the most subtle matter, is highly elastic, and the undulations are propagated through it with great velocity in spherical superficies proceeding from a centre. Light, in this view of it, differs from that of the Cartesian system, which is supposed to be without elasticity, and to convey impressions instantaneously, as a staff does from the object it touches to the hand which holds it.

It is not, however, in this general view, that the ingenuity of the theory appears, but in its application to explain the equality of the angles of incidence and reflection; and, most of all, the constant ratio which subsists between the sines of the angles of incidence and of refraction. Few things are to be met with more simple and beautiful than this last application of the theory; but that which is most remarkable of all is, the use made of it to explain the double refraction of Iceland crystal. This crystal, which is no other than the calcareous spar of mineralogists, has not only the property of refracting light in the usual manner of glass, water, and other transparent bodies, but it has also another power of refraction, by which even the rays falling perpendicularly on the surface of the crystal are turned out of their course, so that a double image is formed of all objects seen through these crystals. This property belongs not only to calcareous spar, but, in a greater or less degree, to all substances which are both crystallized and transparent.

The common refraction is explained by Huygens, on the supposition, that the undulations in the luminous fluid are propagated in the form of spherical waves. The double refraction is explained on the supposition, that the undulations of light, in passing through the calcareous spar, assume a spheroidal form; and this hypothesis, though it does not apply with the same simplicity as the former, yet admits of such precision, that a proportion of the axes of the spheroids may be assigned, which will account for the precise quantity of the extraordinary refraction, and for all the phenomena dependent on it, which Huygens had studied with great care, and had reduced to the smallest number of general facts. That these spheroidal undulations actually exist, he would, after all, be a bold theorist who should affirm; but that the supposition of their existence is an accurate expression

---

[1] Traité de la Lumière. Leyd. 1690.

of the phenomena of double refraction, cannot be doubted. When one enunciates the hypothesis of the spheroidal undulations, he, in fact, expresses in a single sentence all the phenomena of double refraction. The hypothesis is therefore the means of representing these phenomena, and the laws which they obey, to the imagination or the understanding, and there is, perhaps, no theory in optics, and but very few in natural philosophy, of which more can be said. Theory, therefore, in this instance, is merely to be regarded as the expression of a general law, and in that light, I think, it is considered by La Place.

To carry the theory of Huygens farther, and to render it quite satisfactory, a reason ought to be assigned why the undulations of the luminous fluid are spheroidal in the case of crystals, and spherical in all other cases. This would be to render the generalization more complete; and till that is done, and a connection clearly established between the structure of crystallized bodies, and the property of double refraction, the theory will remain imperfect. The attention which at present is given to this most singular and interesting branch of optics, and the great number of new phenomena observed and classed under the head of the *Polarisation of Light*, make it almost certain that this object will be either speedily accomplished, or that science has here reached one of the immoveable barriers by which the circle of human knowledge is to be for ever circumscribed.

Supplement

TO THE

ENCYCLOPÆDIA BRITANNICA.

AUSTRALASIA,

Australasia.

Introductory Observations.

IN Modern Geography, the *fifth* great division of the Earth's surface. A systematic classification in geography is as necessary to enable us to form clear and comprehensive views of its objects, as it is in botany, mineralogy, geology, or any other department of physical science, though incapable of being brought to the same degree of perfection. The rapid progress made, during the last fifty years of the past century, in the discovery of those almost innumerable Islands that are scattered over the three great oceans, the Indian, the Southern, and the Pacific, peopled by various races of human beings, differing in their features, manners, dispositions, and language, forcibly demanded some such systematic arrangement; otherwise, as the President De Brosses has observed, "The sight would be dazzled and confounded, if care were not exerted to relieve it, and fix its attention by divisions marked from distance to distance."

It was this learned and very intelligent writer who first suggested, that all the Lands and Islands in the *Austral* world should be divided into three portions, corresponding with the three great Oceans, the Indian or Ethiopic, the Atlantic, and the Pacific; those in the Indian Ocean, and to the south of Asia, to be named *Australasia;* those in the two Pacifics, from the multitude of Islands, *Polynesia* (a name first used, we believe, by De Barros), and those in the Atlantic, to the south of Cape Horn, and the Cape of Good Hope, *Magellanica.* The last, however, became unnecessary, as soon as it was ascertained, that the *Terra Australis incognita* had no existence. Some idea may be formed of the rapid progress made in maritime geography, even within the last fifty years, and of its imperfection previous to that period, when it is stated, that, in the year 1770, the enlightened and industrious hydrographer, the late Alexander Dalrymple, asserted that the *great southern continent* was not then a matter of *discovery,* for that it had been seen on the west by Tasman in 1642, and on the east by Juan Fernandez, above half a century before; adding, without any doubt or hesitation, that "the countries intermediate, equal in extent to all the civilized part of Asia, from Turkey to China inclusive, still remain unexplored." Nay, more, "that it extended from 30° south to the pole, and that the number of its inhabitants was probably more than fifty millions." All these facts he discovers in the Spanish and Portuguese voyages in the South Pacific Ocean. (*Historical Collections.*)

Australasia.

The two divisions of Australasia and Polynesia will be found to comprehend, with sufficient convenience, all those Islands, that cannot with propriety be referred to any of the four continents of the Globe. Nor is there any difficulty in drawing the line of separation between those two divisions; though it is not quite so easy to mark the distinct boundary between the Australasian and the Asiatic Islands, where they melt into each other, about the Equator, at the north-west extremity of Papua or New Guinea. In a geographical view, the small Islands of Waygiou, Salwatty, Batanta, Mysol, and Timorlaut, ought strictly to belong to Australasia; but peopled, as they are, by Asiatics of the Malay tribe, and under the influence of the Dutch Islands, it may, perhaps, be more proper, in a moral and political point of view,

Australasia. to consider them as belonging to the Asiatic Islands; more particularly, as we shall then have all the Australasian population, with very few exceptions, marked with the African or Negro character. But, in fact, all geographical divisions are and must be to a certain degree arbitrary.

Boundaries. If, then, we take the equator as the northern boundary from the 132° to the 175° of east longitude; continue a line on the latter meridian to the 55th parallel (bending a little to take in New Zealand) for the eastern; another line along the same parallel to the 65° of east longitude for the southern; and a slanting line to the point on the equator from which we set out, so as to include Kerguelen's land, and pass on the eastern sides of Timorlaut, Ceram, Mysol, and Salwatty, for the western boundary;—those lines will circumscribe the whole of the Australasian Islands. We have included the uninhabited Islands of Kerguelen, and St Paul and Amsterdam, because they cannot properly be considered as African Islands; though arranged, we believe, under that division by Pinkerton: they are of less importance to geography than to geology.

Australasia, then, may be subdivided into the following Groups and Islands:

1. Notasia, or New Holland.
2. Van Dieman's land.
3. Papua, or New Guinea.
4. New Britain, New Ireland, and neighbouring Islands.
5. Solomon's Islands.
6. New Hebrides.
7. New Caledonia.
8. New Zealand, and Isles to the southward.
9. Kerguelen's Islands, or Islands of Desolation.
10. St Paul and Amsterdam.
11. Numerous reefs and Islets of Coral scattered over the Australasian Sea.

New Holland. I. The first attempt to explore this Island, which, from its size, may be considered as the fifth continent of the earth, is unquestionably due to the Dutch; for, although some part of the northern coast may have been seen by the early navigators of Spain and Portugal, there is no direct testimony in favour of such discovery. There are two charts in the British Museum which belonged to the *Harleian Collection*, one French, without date, which was probably the original, and the other English, apparently a copy; the latter is dedicated to the King of England, and bears date 1542; in both of these charts is marked down an extensive tract of country to the southward of

Progress of Discovery. the Moluccas, under the name of *Great Java*, agreeing more nearly with the position and extent of New Holland than any other land. The form given to the north-west part of the coast approaches nearest to the truth, a part, indeed, which may have been seen by these early navigators in their return from the Moluccas, long before the date of the English chart. It is a singular coincidence in geographical nomenclature, that on the east coast of the French chart, something like a *Botany Bay* should be designated under the name of *Coste des Herbaiges*. The Abbé Prévost, in the *Histoire Generale des Voyages*, and the President De Brosses, in his *Histoire des Navigations aux Terres Australes*, are not very happy in advancing a claim in favour of Paulovier de Gonneville, a French Captain, to the discovery of this *Terra Australis* in 1504. It was the coast of Madagascar upon which Gonneville, as is evident by their own accounts, was driven.

Australasia.

The best and most authentic abstract of the Dutch discoveries, on the coasts of New Holland, is contained in the instructions given by the Governor-General of Batavia to Commodore Abel Janzen Tasman, and published by Mr Dalrymple in his *Collection concerning Papua*. From this document, it appears, that the Dutch government of Bantam, in 1605, dispatched the Duyfhen yacht to explore the Islands of New Guinea. Returning to the southward, along the Islands on the northern side of Torres' Strait, she came to that part of the *Great South Land*, which is now called Cape York; but all these lands were then thought to be connected, and to form the southern coast of New Guinea. "Thus," says Captain Flinders, "without being conscious of it, the commander of the Duyfhen made the first authenticated discovery of any part of the *Great South Land*, about the month of March 1606." About the same place, and in the same year, Torres, a Spanish navigator, being second in command to Fernandez de Quiros, saw the *Terra Australis*, but had as little knowledge of the nature of his discovery as the commander of the Duyfhen. He passed the strait, however, which divides this *Terra Australis* from New Guinea, whose existence was not generally known till 1770, when it was again discovered and passed by our great circumnavigator Captain Cook. Of this, and his other discoveries, Torres addressed an account to the King of Spain; and, as it afterwards appeared, had taken the precaution to lodge a copy of it in the archives of Manilla; for, when that city was surrendered to the British forces in 1762, Mr Dalrymple snatched from oblivion this interesting document of early discovery; and as a just tribute to the enterprising Spanish navigator, he gave to this passage the name of *Torres Strait*, by which it is now universally known.

In 1617 the Dutch sent a second expedition, but "with little success;" the journals of which were lost. In 1623, the yachts Pera and Arnheim were dispatched from Amboyna, under the command of Jan Carstens, who, with eight of the Arnheim's crew, was treacherously murdered by the natives of New Guinea; but the vessels prosecuted the voyage, and discovered the great Islands Arnheim and the Spult. The Arnheim returned to Amboyna; the Pera persisted, and ran along the west coast of New Guinea, as they thought, but it was New Holland, to Cape Keer-veer, or Turn-again, and from thence explored the coast farther southward, as far as 17°, to Staten River. "In this discovery were found everywhere shallow water and barren coasts, Islands altogether thinly peopled by divers cruel, poor, and brutal nations; and of very little use to the (Dutch East India) Company."

The next expedition sent by the Dutch was from Banda in the year 1636, when Gerrit Tomaz Pool proceeded with the yachts Klein Amsterdam, and Wesel, and nearly at the same place, on the coast of

From M.r Arrowsmith's Chart of the Pacific Ocean.

S.d Hall sculp 14 Bury Str. Bloomsbury.

New Guinea, met the same fate which had befallen Carstens; but the supercargo, Pieterson, continued the voyage, and discovered the coast of Arnheim, or Van Dieman's land, in 11° south, and sailed along the shore 120 miles, without seeing any inhabitants.

Abel Jansen Tasman sailed on a second voyage of discovery from Batavia in 1644, but no account of this voyage was ever made public, nor is it known to exist. No chart bearing his name is now known, but there is little doubt that the north-west coast of New Holland was first explored by him; and it is singular enough, that Dampier should say he had Tasman's chart of it. Tasman is also supposed to have sailed round the Gulf of Carpentaria, an opinion which Captain Flinders considers to be strengthened, from the names of Tasman, of the governor-general, and of two of the council, who signed his instructions, being applied to places at the head of the gulf, as well as that of Maria, the governor's daughter, to whom Tasman is said to have been attached. Tasman had sailed, on a former voyage, from Batavia in 1642, for the Mauritius; from hence steering south and eastward upon discovery, he fell in with land, to which he gave the name of *Anthony Van Dieman's Land*, in honour of the governor-general, "our master," he adds, "who sent us out to make discoveries."

The last voyage undertaken by the Dutch, for the discovery of *Terra Australis*, was in 1705, when three Dutch vessels were sent from Timor, "with orders to explore the north coast of New Holland better than it had been done before." The account, however, given by the President De Brosses is so vague and imperfect, that very little satisfactory information is to be obtained from it. It is on the west coast that the Dutch appear to have been most successful. In Tasman's instructions it is stated, that "in the years 1616, 1618, 1619, and 1622, the west coast of this great *unknown* southland, from 35° to 22° south latitude, was discovered by outward bound ships, and among them, by the ship *Endragt*." Dirk Hartog commanded this ship, and seems to have made the coast in latitude about 26½° south, and to have sailed northward, along it, to about 23°; giving the name of *Landt van Endragt* to the coast so discovered; and that of Dirk Hartog's road (called afterwards *Shark's Bay* by Dampier) to an Inlet on the coast, a little to the southward of 25°. A plate of tin was found in 1697, and again seen by Baudin in 1801, on one of the Islands which forms the roadstead, bearing an inscription that the ship Endragt of Amsterdam arrived there on the 25th October 1616. After this several outward bound ships fell in, by accident, with different parts of this coast.

The Dutch made little progress in any other part of the extensive coasts of New Holland. The instructions to Tasman say, "In the year 1627, the south coast of the Great South Land was accidentally discovered by the ship the Guldee Zeepard, outward bound from Fatherland, for the space of 1000 miles." From the circumstance of this ship having on board Pieter Nuyts, who was sent from Batavia as ambassador to Japan, and afterwards appointed governor of Formosa, the name of *Nuyts' Land* was given to this long range of coast.

The first English navigator who appears to have seen any part of New Holland, is the celebrated William Dampier, who, in his buccaneering voyage round the world, in January 1668, touched at the north-west coast, for the purposes of careening his vessel and procuring refreshments. He made the land in latitude 16° 15′, and ran along the shore to the north-east, till he came to a bay or opening fit for the purpose. In 1699, Dampier, a second time, visited the north-western coast of this *Terra Australis*, being now legitimately employed in making discovery, in his Majesty's ship the Roebuck. Of this part of the coast little more is yet known than what has been described by Dampier.

It was left for our celebrated navigator, Captain Cook, to complete the grand outline of the fifth continent of the world. The reign of George III. will ever be distinguished for the liberal principles on which voyages of discovery were undertaken, and their results communicated to the world. The Endeavour was fitted out to observe, at Taheité, the transit of Venus over the sun's disk; on her return, in 1770, Captain, then Lieutenant Cook, explored the whole east coast of the *Terra Australis incognita*, from Cape Howe to Cape York, not minutely entering into the details of every part, which would have been impossible, but laying down a correct general outline. "He reaped," says Captain Flinders, "the harvest of discovery, but the gleanings of the field remained to be gathered." In his passage through Endeavour's Strait, between Cape York and the Prince of Wales' Islands, he not only cleared up the doubt which till then existed, of the actual separation of *Terra Australis* from *New Guinea*, but, by his accurate observations, enabled geographers to assign something like a true place to the former discoveries of the Dutch in these parts.

In 1777 Captain Cook, in the *Resolution* and *Discovery*, visited Van Dieman's Land; but as Captain Furneaux, in his Majesty's ship *Adventure*, had preceded him four years, and Tasman and Marion had examined the coast, little was here supposed to remain for discovery, except in detail. It was long subsequent to Furneaux's visit, that Van Dieman's Land was ascertained to be an Island; a discovery which may have been retarded by that officer having given an opinion, "that there is no strait between New Holland and Van Dieman's Land, but a very deep bay." The existence of such a strait was however still suspected, but the various attempts to ascertain it, without success, by different navigators from both sides of the coast, seemed to have decided the question in the negative, when Mr Bass, surgeon of the Reliance, having observed, as he ran down the east coast in an open whale boat, that a heavy swell rolled in from the westward, was satisfied in his own mind that such a swell could proceed only from the great Southern Ocean. To ascertain whether this was the fact, was a point of great importance to the new colony on the eastern coast; and for this purpose Mr Flinders, together with Mr Bass, were sent on this service in a small decked boat;—at the end of three months, they returned to Port Jackson, with an interesting account of the survey of the coasts of Van Dieman's Land, which they had completely cir-

cumnavigated, and thus confirmed the conjecture of Mr Bass, whose name the strait deservedly bears.

The French are entitled to the honour of some partial discoveries on *Terra Australis*. Captain Marion was dispatched in the year 1772 from the Isle of France with two ships, the *Mascarin* and *Marquis de Castries*, on a voyage of discovery, one of the objects of which was that of the supposed southern continent. He touched at Van Dieman's Land, quarrelled with the natives, and finding no fresh water, and the weather being stormy, he set sail for New Zealand, having added very little to the prior discoveries of Tasman.

In the year 1792, Rear-Admiral D'Entrecasteaux, having been sent out with two ships, *La Recherche* and *L'Esperance*, in search of the unfortunate La Perouse, made the south coast of New Holland, which he explored as far as the Termination Island of Vancouver, the deficiencies of whose chart he was able to supply, by the state of the weather permitting him to keep the coast closer on board than the English navigator had been able to do. Termination Island was found to be the first of a large group laid down by Nuyts, whose accuracy is praised by the Admiral, he having found " the latitude of Point Leuwen and of the coast of Nuyts' Land laid down with an exactness surprising for the remote period in which they had been discovered." This liberal acknowledgment did not, however, prevent him from giving to the group of Islands, which he only saw, but did not survey, the name of *Archipel de la Recherche*. But the most important discovery of D'Entrecasteaux was an inlet on the south coast of Van Dieman's Land, which was found to be the entrance into a fine navigable channel, running more than thirty miles to the northward, and there communicating with Storm Bay; containing a series of excellent harbours, or rather one continued harbour the whole way, from beginning to end. " The charts," says Captain Flinders, " of the bays, ports, and arms of the sea, at the south-east end of Van Dieman's Land, constructed, in this expedition, by Monsieurs Beautemps, Beaupré, and assistants, appear to combine scientific accuracy and minuteness of detail, with an uncommon degree of neatness in the execution. They contain some of the finest specimens of marine surveying, perhaps, ever made in a new country."

In 1800, Captain Baudin was sent out with two armed vessels, *Le Geographe* and *Le Naturaliste*, on a voyage of discovery nominally *round the world*, but actually, as appears from his instructions, to examine every part of the coasts of New Holland and Van Dieman's Land. The first volume of the account of this voyage was published by M. Peron, one of the naturalists, in 1807; the second never appeared. All the old names of the capes, bays, inlets, and islands, were unblushingly changed to those of Napoleon, his family, his marshals, and members of the Institute; and to 900 leagues of the southern coast, comprehending all the discoveries of Nuyts, Vancouver, D'Entrecasteaux, Flinders, Bass, and Grant, was given the general name of *Terre Napoleon*, while not 50 leagues of real discovery were effected, which had not been anticipated by Captain Flinders; who, after losing his ship, and proceeding homewards, was scandalously detained as a prisoner in the Isle of France, "to give time for the previous publication of the voyage of M. Baudin, to prepossess the world, that it was to the French nation only the complete discovery and examination of the south coast of Australia was due."

Captain Flinders, however, ultimately triumphed. After an unjust and cruel captivity of seven years, he arrived in England in 1810, and in 1814 published his discoveries in two volumes, accompanied with an atlas of charts, which may be held forth as models in maritime surveying. At this time, not a single chart of coast, bay, or island, of Captain Baudin's discoveries had appeared, though shortly afterwards, an atlas was published by Freycinet, the first lieutenant, differing in their form and structure very little from those of Captain Flinders, but bearing the names recorded in M. Peron's first volume. The frontispiece to this atlas affords an instance of that almost impious adulation which Buonaparte was in the habit of receiving from his slaves. An *eye*, having an N within it, darts its rays through a dark cloud overshadowing a Globe with the southern pole uppermost, on which is drawn the outline of New Holland, with this inscription, " *Fulget et ipso*."

It is to Captain Flinders that we owe the completion in detail of the survey of the coasts of New Holland, with the exception of the west and north-west coasts, which he was prevented from accomplishing by the loss of his ship. Dampier had said, in anchoring near the south end of De Witt's Land, behind Rosemary Island, which was one of an extensive cluster, " by the tides I met with a while afterwards, I had a strong suspicion that there might be a kind of archipelago of Islands, and a passage possibly to the south of New Holland and New Guinea, into the Great South Sea eastward;" but whether it might be a channel or strait, or the mouth of a large river, he seems not to have made up his mind. Vlaming saw an opening 12 miles wide near the same place, and could find no anchorage. It has now been ascertained, that there is no outlet into the great Ocean eastward, nor into the gulf of Carpentaria, nor into Bass Strait; but the geographical problem yet remains to be solved, whether the opening in the coast behind Rosemary Island be not the mouth of a large river. *Le Geographe* and *Le Naturaliste*, under Baudin, stood along this coast, examined in a very slovenly manner some particular points, but assisted geography less than they perplexed it, by unwarrantably changing every old name for that of some of the upstarts created by the French revolution. Never, indeed, were two naval officers so ill selected for the purpose of discovery as Captains Baudin and Hamelin; not so those in the scientific department, who, under every unfavourable and discouraging circumstance, effected more for physical science than could be expected. The whole of this coast then may still be considered as *terra incognita*; and it is somewhat remarkable, that the local government of New South Wales, which, we believe, has under its command several colonial vessels, should not before this have taken occasion to ascertain this

Australasia.

point, on which so many curious and unexplained phenomena in the geography and geology of the fifth continent depend. It is no less remarkable, that in a period not far short of thirty years since the settlement of Port Jackson was first made, all beyond as many leagues was a complete *terra incognita* to the settlers, till about two years ago, when Mr Evans, the land-surveyor, penetrated behind the hitherto impassable barrier, the Blue Mountains, to the distance of about 300 miles in two separate journeys.

Journeys in the Interior.

Of these journeys we are enabled to give a brief abstract. On the 19th November 1813, Mr Evans left Emu Island in the Nepean, and returned on the 8th January 1814, having performed a journey of 154 miles nearly west. At the end of 48 miles, he had cleared the ranges of mountains, which he says are granite, with loose flints and quartz pebbles strewed on the surface; and here, for the first time, he fell in with a small stream running to the westward. The farther he advanced the more beautiful the country became; both hill and dale were clothed with fine grass, the whole appearing at a little distance as if laid out into fields divided by hedgerows; through every valley meandered trickling streams of fine water, all falling down towards the *Fish River*, so called by him from the vast abundance of fine fish resembling trout, which his party caught with ease whenever they had occasion for them. Many of the hills were capped with forest trees, chiefly of the Eucalyptus, and clumps of these mixed with Mimosas and the Casuarina, were interspersed along the feet of the hills and in the valleys, so as to wear the appearance of a succession of gentlemen's parks. The river, which at first consisted of a chain of pools, connected by small streamlets, had assumed in the neighbourhood of *Macquarrie's Plains*, the character of a considerable stream, and had become unfordable, which made it necessary to construct a bridge of large trees to transport the people, the horses, and baggage. Evans says, the country was now more beautiful than he had ever seen. A fine river, running in a deep channel over a gravelly bottom, and its banks skirted with trees, excepting at the sloping points of hills round which it winded, and which were covered with a fine green sod down to the margin, intermixed with the white daisy;—all this, added to the temperate climate, put him in mind of England. Farther on, and before they reached *Bathurst's Plains*, the river was increased considerably in size by the junction of another stream, which he called *Campbell's River*; and to the united streams, he gave the name of *Macquarrie's River*, the general direction of which appeared to be to the northward of west. Fish continued to abound of the same kind as those first caught, but of a size from 11 to 15 pounds each. Governor Macquarrie says, these fish resemble perch, are not unlike that usually called rock-cod, and have been caught from 17 to 25 pounds weight each. Large herds of emus were seen crossing the plains, and kangaroos in great abundance; but not a native human being appeared until on his return, when, near *Bathurst's Plains*, two women and four children were come upon by surprise, and were so terrified, that they fell down with fright. It was observed, that both the women had lost the right eye. Evans makes Bathurst's Plains near 150 miles from Emu Island; but Governor Macquarrie, who subsequently visited this place, states the measured distance from Sydney town to be only 140 miles. It is represented as an eligible situation for establishing a settlement, as the land is excellent; plenty of stone and timber for building, but no limestone; abundance of water, though the river, at the time of the Governor's visit, just at the close of an unusually dry season, was reduced to a chain of pools, the intermediate channels being dried up.

Australasia.

From hence Mr Evans was a second time dispatched, in May 1815, to follow the course of Macquarrie's River. He proceeded about 115 miles, from whence he could see across an extensive plain, 40 or 50 miles, at the extremity of which was a range of blue mountains, separated by an opening in the north-west, through which, he had no doubt, the river flowed; and he appears to have as little doubt, that it crosses the continent, and falls into the sea, somewhere in De Witt's Land, probably through Dampier's Opening, behind Rosemary Island.

From these journeys, it appears clear that the country is but thinly peopled. The natives that were seen resembled, in their persons and features, those of Sydney, but spoke a different language; and they were better clothed, being well covered with kangaroo skins, sewed neatly together with the sinews of emus. They wore the fur side next the skin, and the outer or flesh side was very ingeniously marked with regular ornamental devices, among which the *cross* appeared to predominate. They were exceedingly terrified at the sight of Mr Evans on his horse, as they took the rider and horse to be one animal, and did not recover from their fright or surprise on seeing him dismount. When a little tranquillized, and more familiar, they were found to be a good-humoured laughing people, exhibiting none of that savage and furious spirit of the natives of Sydney. They were attended with dogs not unlike the jackall, with which they catch kangaroos. The spears they carried were heavy, and clumsily made, and they could only throw them to a short distance, something like the New Zealanders.

The country beyond *Bathurst* was even superior to that first explored. The vast herds of emus and kangaroos were truly astonishing. These animals, and the fish of the river, appeared to be the principal articles of subsistence for the natives. In one large plain, covered with kangaroos and emus, Evans discovered an immense quantity of a white substance, resembling comfits or sugar-plums, which he took to be manna, but which appears to be a pure saccharine substance,—an exudation probably from some particular plant. He passed whole mountains of fine blue limestone, and picked up topazes, crystals, and other pebbles, such as are met with on the coast of Bass's Strait. He also mentions forests of pines, the trees 40 feet high without a branch. Governor Macquarrie, however, observed, that as the soil and grass-lands improved, the timber trees decreased in size. (See the different works of *Dalrymple*, *Burney*, *Cook*, *D'Entrecasteaux*, and *Flinders*.)

If, however, but little is yet known of the interior

Australasia.

General View of New Holland.

of New Holland, and the detail of the western coast still requires to be filled up, the grand outline of this large Island, or, more properly, Continent, has been completed, and its limits correctly ascertained. It extends in latitude from Cape York in 10° 45′ south to Wilson's promontory in 39° 9′ south, and in longitude from Dirk Hartog's Island in Shark's Bay in 113° east, to point Look-out in Glasshouse Bay in 153° 35′ east; the mean breadth, from north to south, being about 1200, and length, from east to west, 2100 geographical miles, making an area equal to about three-fourths of the Continent of Europe. A remarkable sameness in all the productions of the three kingdoms of nature prevails in every part of its extensive coasts, and as remarkable a difference in two of them (the animal and vegetable) from those of the rest of the world.

Natives.

The natives, wherever they have been met with, are of the very lowest description of human beings. In the journal of the Duyfhen, the north coast is described as thinly "inhabited by wild, cruel, black savages, by whom some of the crew were murdered;" and the ship Vianen, touching on the western coast about 21° south, observed "a foul and barren shore, green fields, and very wild, black, barbarous inhabitants." In 24° south, Polsert, who commanded the Batavia, saw four natives, whom he describes as "wild, black, and altogether naked, not covering even those parts which almost all savages conceal." Tasman "found in *Hollandia Nova*, in lat. 17° 12′ south, a naked black people, with curly hair, malicious, and cruel, using for arms bows and arrows, hazagaeys and kalawaeys." Dampier describes them as being "a naked black people, with curly hair, having a piece of the rind of a tree tied like a girdle about their waists, and a handful of long grass, or three or four green boughs full of leaves thrust under their girdle to cover their nakedness;" that "the two fore-teeth of the upper jaw are wanting in all of them, men and women, old and young; neither have they any beards." And he remarks, "they have no boats, canoes, or bark-logs." The south coast is so barren, and the naked hillocks of sand so continuous, that there appears to be nothing for human inhabitants to subsist upon. "It is not surprising," says D'Entrecasteaux, "that Nuyts has given no details of this barren coast; for its aspect is so uniform, that the most fruitful imagination could find nothing to say of it." Even where the country begins to improve towards the eastward, in the neighbourhood of Kangaroo Island, Captain Flinders found not the least vestige of inhabitants; and, from the stupidity of the kangaroos on that Island, "which," he observes, "not unfrequently appeared to consider us as seals," he concludes there either are no natives, or that they are ignorant of every kind of embarkation. Towards the northern part of the eastern coast, the same navigator thinks they are somewhat superior to those near Sydney, having belts round the waist, and fillets about the head and upper part of the arm, associating in greater numbers, and dwelling in huts of a superior construction. They also catch fish with nets, which he thinks is alone a feature of distinction from those who only spear the fish, as a net requires more than one person to manage, consumes much time in making, cannot easily be dragged about, and, in short, must occasion a sense of the advantage to be derived from mutual assistance, and suggest the necessity of a permanent residence. The native of the colony of Sydney we know pretty well to be a gloomy, solitary, unsettled being; seldom appearing, even in the town, without his spear, his throwing-stick, or his club. "His spear," says Colonel Collins, "is his defence against enemies. It is the weapon he uses to punish aggression, and revenge insult. It is even the instrument with which he corrects his wife in the last extreme; for, in their passion, or perhaps oftener in a fit of jealousy, they scruple not to inflict death. It is the plaything of children, and in the hands of persons of all ages." Turnbull says, the natives of this part of New Holland are, beyond comparison, the most barbarous on the surface of the Globe, and that the influence of European settlers has had no effect in rendering them more sensible of the benefits of civilization; that every day men and women are to be seen in the streets of Sydney and Paramatta naked as in the moment of their birth; yet he contends that they are far from being stupid; that they are the greatest mimics alive; and that the oddities, dress, walk, gait, and looks of all the Europeans of any rank, from the time of Governor Phillip downwards, are so exactly imitated, as to form among them a kind of historic register of their several actions and characters; and they are great proficients in the slang language of the convicts. But this seems to be the sum total of all their acquisitions from European intercourse. In all other respects they remain the same untutored, unprotected, improvident, and comfortless savages we first found them. By all who have seen them they are described as hideously ugly, with flat noses, wide nostrils, eyes sunk in the head, overshadowed with thick black eyebrows; the mouth extravagantly wide, lips thick and prominent, hair black and clotted, but not woolly, the colour of the skin varying from dark bronze to jet black. Their stature is below the middle size. They are remarkably thin and ill made, their limbs small, and almost without any appearance of muscle. They live chiefly on fish, which they sometimes spear and sometimes net, the women on parts of the coast aiding to catch them with the hook and line. If a dead whale happens to be cast on shore, numbers flock to it from every part of the coast, just as the vultures smell out a dead carcase, and they feast sumptuously while any part of it remains. Those in the interior are stated to live on grubs, ants and their eggs, kangaroos, when they can catch them, fern roots, various kinds of berries, and honey. These sylvan satyrs are described as having long and lean legs and arms, owing, as is supposed, to their climbing of trees, which they ascend by notches cut into them by stone hatchets, in which the great toe is placed, and by these means they ascend trees that are 70 or 80 feet high.

To add to their natural deformity, they thrust a bone through the cartilage of the nose, and stick with gum to their hair, matted with moss, the teeth of men, sharks, or kangaroos, the tails of dogs, jawbones of fish, &c. and daub their faces and bodies

Australasia. with red and white clay, and scarify the skin in every part with sharp shells. The women and female children are generally found to want the first two joints of the little finger of the left hand; and the reason they assign is, that they would otherwise be in the way of winding the fishing-lines over the hand.

They have no fixed habitations, the climate generally allowing of their sleeping in the open air, in the crevices of rocks, or under the shelter of the bushes. Their temporary hovels consist of the bark of a tree, each hovel just large enough to receive a single person; to the northward, on the east coast, some were discovered a little larger, so that a family might, on an emergency, squeeze under one of them; but they are without furniture or conveniences of any description. They seem to have no idea of the benefits arising from social life; their largest clans extend not beyond the family circle, of each of which the eldest is called by a name synonymous with that of *father*. They are totally without religion, neither paying the least respect or adoration to any object or being, real or imaginary. Hence they have nothing to prompt them to a good action, nothing to deter them from a bad one; hence murder is not considered as any heinous crime, and women think nothing of destroying, by compression, the infant in the womb, to avoid the trouble, if brought alive into the world, of carrying it about and finding it subsistence. Should a woman die with an infant at the breast, the living child is inhumanly thrown into the same hole with the mother, and covered with stones, of which the brutal father throws the first. They are savage even in love, the very first act of courtship, on the part of the husband, being that of knocking down his intended bride with a club, and dragging her away from her friends, bleeding and senseless, to the woods; the consequence is, that scarcely a female of the age of maturity is to be seen without her head full of scars, the unequivocal marks of her husband's affection. The nearest relations are also perpetually destroying each other, either by stratagem or open combat; for, savage as they are, they have a singular custom of expiating an offence, even murder, by the criminal exposing himself to as many of the injured family as may choose to stand forth and hurl their spears at him. From the moment that he is so dreadfully mangled that he can stand no longer, or has the good fortune to parry all their shafts, a reconcilement takes place, and friendship is restored; if the criminal refuses to stand this trial, he and all his family are considered as fair game to attack and murder wherever they are met with. The English used to attend these unequal combats, and thus gave countenance to a savage practice, which not unfrequently ended in the death of the person who was put on his defence. (See *Collins, Flinders, Turnbull,* &c.)

Animals. If no very essential difference be perceptible in the moral and physical qualities of the man of New Holland, and the rest of the species, except that which arises from the different circumstances under which they are placed;—if the rocks and mountains, and the earths, resemble nearly the inorganic substances that are met with in other parts of the world, there is at least a very extraordinary, and a distinct characteristic difference in both the animal and vegetable part of the creation, which makes a considerable class of subjects in both these kingdoms peculiar to New Holland. The quadrupeds hitherto discovered, with very few exceptions, are of the kangaroo or opossum tribe; having their hinder legs long out of all proportion, when compared with the length of the fore legs, and a sack under the belly of the female for the reception of the young, of which family, though divided into different genera, there are at least fifty distinct species. They have rats, and dogs of the jackall kind, all exactly alike, and a little animal of the bear tribe named *womat*, and these pretty nearly complete the catalogue of four-footed animals yet known on this fifth Continent. There appears, indeed, such an apparent affinity of the natural objects in New South Wales, that Dr White observes, all the quadrupeds are like opossums, all the fish like sharks, and that every part of the land, all the trees, and all the grasses, resemble one another. There is, however, an animal which resembles nothing in the creation but itself,—which, being rejected by naturalists from the classes mammalia, aves, and pisces, must, we suppose, be considered as belonging to the amphibia,—we mean the Ornithoryncus paradoxus, "a quadruped with the beak of a bird, which is contrary to known facts and received opinions." When the head of one of these beasts was brought to the late Dr Shaw, of the British Museum, he suspected it as an idle attempt to impose on his judgment, and did not hastily believe that nature had set the bill of a duck on the head of a quadruped; but so it has since proved to be the case.

The birds are no less singular than the beasts, there being black swans and white eagles; the former everywhere in such multitudes as to spoil a proverb that had held good for two thousand years; and their song, if we may credit Mr Bass, "exactly resembles the creaking of a rusty sign on a windy day." The *Mænura superba*, with its scalloped tail feathers, is perhaps the most singular and beautiful of that very elegant race of birds known by the name of *birds of paradise*; cockatoos, parrots, and parroquets, are innumerable, and of great variety. The mountain eagle is a magnificent creature, but the emu is perhaps the tallest and loftiest bird that exists, many of them standing full seven feet high.

The plants are no less singular than the animals. Plants. Of these Mr Brown has given a very curious and instructive account in his *Geographical and Systematical Remarks*, in the *Appendix to Flinders's Voyage*. He collected nearly 3900 species of Australasian plants, which, with those brought to England by Sir Joseph Banks and others, supplied him with the materials for a *Flora Terræ Australis*, consisting of 4200 species, referable to 120 natural orders: but he remarks, that more than half the number of species belong to *eleven* only of those orders. Of the *Eucalyptus*, or gum-tree, the largest yet discovered, there are not fewer than 100 different species. "The *Eucalyptus globulus* of Labillardiere," says Mr Brown, "and another species, peculiar to the south of Van Dieman's Land, not unfrequently attain the

Australasia.

height of 150 feet, with a girth near the base of from 25 to 40 feet." Of this magnificent genus there are 50 different species within the limits of the colony of Port Jackson. Of the beautiful and elegant *Melaleuca* Mr Brown collected upwards of 30 species; all of which, with the exception of the two species the *Leucodendron* and *Cajaputi*, appear to be confined to Terra Australis. The tribe of *Stackhouseæ* is entirely peculiar to that country. Of the natural order of *proteaceæ*, consisting of about 400 known species, more than 200 are natives of New Holland, of which they form one of its characteristic botanical features; the *Banksia*, in particular, being one of the most striking peculiarities of the vegetable kingdom. The *Casuarina*, of which 13 species have been discovered, is another characteristic feature of the woods and thickets of New Holland. The most extensive genus, however, is the leafless *Acacia*, of which there are more than 100 species; and this, with the *Eucalyptus*, "if taken together," says Mr Brown, "and considered with respect to the mass of vegetable matter they contain, calculated from the size as well as from the number of individuals, are perhaps nearly equal to all the other plants of that country." The *Casuarina* and the *Eucalyptus* are represented as furnishing excellent timber for ship-building, and for all the purposes of domestic furniture, and agricultural implements; and the gum of the *Eucalyptus* is medicinal; of one species it might be employed as pitch. Freycinet says, they procured a resinous substance from the *Xanthorrhea*, which served them to caulk their vessels. The bark of a tree on the Hawkesbury is said to be as efficacious in tanning leather as the oak-bark; and a creeping plant *(smilax)* is used as a substitute for tea. Nutmegs were found by Flinders on the northern coast, but they were small, and had so little of an aromatic flavour, that Mr Brown gave the plant the specific name of *insipida*. Among the curious productions of the vegetable world is the *Cephalotus follicularis*, or pitcher plant, of which a very correct and detailed drawing is given in the Atlas to Flinders's *Voyage*. (For an account of the history of the British Colony in New Holland, see New Holland in the *Encyclopædia;* and Botany Bay, in this Supplement, for an account of its present state.)

Van Dieman's Land.

II. Having marked the progressive discovery of this fair and fertile Island, until it was ascertained to be such, by Tasman, Marion, Furneaux, Cook, D'Entrecasteaux, Bass, and Flinders; we shall not think it necessary to notice the minor discoveries of Bligh, Hunter, Cox, &c. but proceed to give a general outline of its dimensions, surface, and natural productions.

General View of this Country.

It is situated between the parallels of 41° and 43° 32′ south latitude, and 144° 32′ and 148° 25′ east longitude; its medial length, from north to south, being about 160, and breadth, from east to west, 145 geographical miles. Its surface possesses every variety of mountain, hill, and dale; of forests and open meadows; of inland lakes, rivers, and inlets of the sea, forming safe and commodious harbours, that can render a country valuable or agreeable; and it enjoys a temperate climate, which is, perhaps, not very different from that of England, though less subject to violent changes. In May, corresponding to our November, Labillardiere observed the mountains in the interior covered with snow. The western and southern coasts are bold, steep, and rocky, the latter terminating so abruptly, as to appear as if it had been broken off: and the group of Islands, named De Witt's Isles, to the southward, twelve in number, formed out of the fragments. Cook found the cliffs on the eastern side composed of sandstone; but the vast buttresses that look towards the southern seas of ice, are stated by Flinders to be composed of basaltic columns, appearing like so many stacks of chimneys. Labillardiere found, near this southern extremity, a stratum of coal 3½ feet thick, and 200 fathoms long, resting on sandstone.

The soil in general is represented as more productive than that of the east side of New Holland; and the Island has the advantage of being intersected by two fine rivers, rising near the centre: the one named the Tamar, falling into Bass's Strait on the north, and forming Port Dalrymple; the other, the Derwent, which discharges itself into the sea on the south-east extremity; spreading its waters, in the first instance, over the Great Storm Bay, which communicates with North Bay, Norfolk Bay, and Double Bay, on the east; and with D'Entrecasteaux's Channel on the west. The Tamar, in its course, receives three streams,—the North Esk, the South Esk, and the Lake river; and the tide flows about 30 miles up the river, to the point where it is joined by the two Esks. At the head of the western arm of Port Dalrymple, is situated York town, on the skirt of a beautiful, rich, and well wooded country. There is also a town, named Hobart town, on the right bank of the Derwent, about five miles inland. The country between these two towns was traversed by Mr Grimes in 1807, who describes it to be everywhere rich and beautiful, abounding in grassy plains, marshes, and lakes, bounded on each side by hills, well clothed with wood, rising into high and rocky mountains.

The description given by D'Entrecasteaux of the channel that bears his name, and the surrounding shores, is grand and imposing, and corresponds generally with the following animated account of it from M. Peron, ten years afterwards. "Crowded on the surface of the soil are seen on every side those beautiful *Mimosas*, those superb *Metrosideros*, those *Correas*, unknown till of late to our country, but now become the pride of our shrubberies. From the shores of the ocean to the summits of the highest mountains, may be observed the mighty *Eucalyptus*, those giant trees of Australasian forests, many of which measure from 162 to 180 feet in height, and from 25 to 30, and even 36 feet in circumference. *Banksia*, of different species, the *Protea*, the *Embothria*, the *Leptosperma*, form an enchanting belt round the skirts of the forests. Here the *Casuarina* exhibits its beautiful form: there the elegant *Exocarpus* throws into a hundred different places its negligent branches. Everywhere spring up the most delightful thickets of *Melaleuca*, *Thesium*, *Conchyum*, *Evodia*, all equally interesting, either from their graceful shape, the lovely verdure of their foliage, the singularity of their corollas, or the form of their seed-vessels." *(Voy. aux Terres Aust.)*

Australasia. Natives.

All the navigators who have visited the southern part of Van Dieman's Land, describe the natives as a mild, affable, good-humoured, and inoffensive people, with the exception of Marion, the effect of whose fire-arms, Labillardiere thinks, had made them afraid of Europeans. Flinders and Bass conceived, that the natives of this Island were sunk still lower in the scale of human existence than those in the neighbourhood of Port Jackson, though they saw but one man, and he is described as having " a countenance more expressive of benignity and intelligence than of that ferocity or stupidity which generally characterized the other natives." They are obviously the same people as those of New Holland, and go entirely naked, both men and women; but their language is altogether different; they have the art, too, of striking fire with two flints, which is not known to the other Australasian islanders; and it is also singular, that they set no value on iron. The women refused from Cook's people all presents, and rejected all their addresses, not so much from a sense of virtue, it was supposed, as from the fear of the men, of whom they stood in great awe. In some places were found miserable huts of twigs, and rude baskets, made of a juncus, or rush; but these were all the signs that appeared of civilization. Cook, D'Entrecasteaux, and Baudin, all observed many of the largest trees, with trunks hollowed out, apparently by means of fire; and, as the hollow side invariably faced the east and south-east, the lee-side to the prevailing winds, it was concluded they were intended as habitations. In D'Entrecasteaux's Channel only were indications of huts made of the bark of the *Eucalyptus*, consisting of three rolls stitched together. (*D'Entrecasteaux, Labillardiere, Flinders*, &c.)

Papua or New Guinea.

III. This great Island is, after New Holland, not only the first in point of magnitude, but claims a priority in discovery over that and every other Island in the Australasian Sea. In the year 1526, when the Portuguese and the Spaniards were disputing their respective claims to the Spice Islands, Don Jorge de Meneses, of the former nation, had, in his passage from Malacca to the Moluccas, by extraordinary and accidental circumstances, discovered the north coast of Papua, so called, according to some, because the word signifies *black*, which was the colour of the natives, or *curled hair*, according to others. Meneses remained at a port called Versija, till the change of the monsoon, and then returned to the Moluccas. The next navigator who touched at Papua was Alvarez de Saavedra, on his homeward voyage from the Moluccas, in 1528, for New Spain; and from an idea that the country abounded in gold, he gave to it the name of *Isla del Oro.* From the resemblance of the natives to African Negroes, being black, with short curly hair, the name was afterwards changed by the Spaniards to New Guinea, and not, as some have supposed, because it was thought that Guinea and Papua were situated under the same parallel of latitude; which, however, they certainly are, though one happens to be north and the other south latitude. He staid a month, and obtained provisions, but some Portuguese deserted with the only boat the ship had, and were left behind. They found their way, however, to Gilolo, and reported that Saavedra had been wrecked; but on his subsequent arrival they were tried, condemned, and executed. He is supposed to have added about 50 leagues of discovery to that of Meneses. In 1529, Saavedra sailed a second time for New Spain, and, according to Galvaom (or Galvano), followed the coast of Papua eastwards above 500 leagues.

Progress of Discovery.

In 1537, Gonzalva and Alvarado were dispatched on discovery by the Viceroy of Peru; but the former being killed in a mutiny, the crew chose another commander; and the first land they made was Papua. The ship was in so crazy a state, that she was abandoned; the crew, only seven in number (the rest having died of hunger and fatigue), were made captives, and carried to an Island called *Crespos* (curly haired men), from whence they were sent to the Moluccas and ransomed.

In 1545, Ynigo Ortiz de Retz, in his voyage from Tidore to New Spain, came to an Archipelago of Islands near the land of Papua; sailed 230 leagues along the north coast; and not knowing it had been before visited by Europeans, he called it *Nueva Guinea*, from the resemblance of the natives to those of the coast of Guinea.

In 1606, Torres made the east coast of New Guinea, in his way to the Moluccas, sailed westward 300 leagues, doubled the south-east point, sailed along the southern coast, saw the northern coast of New Holland, and passed the Strait which now bears his name. He describes the coast of New Guinea to be inhabited by a dark people, naked, except a covering round the middle of painted cloth made of the bark of a tree. They had arms of clubs and darts ornamented with feathers. He fell in with many large islands, large ports, and large rivers. Towards the northern extremity he met with Mahomedans, who had swords and fire-arms.

In 1616, Schouten came in sight of a burning mountain on the coast of New Guinea, which he named Vulcan, and immediately after of the coast itself. The Island was well inhabited, and abounded with cocoa nuts, but no anchoring ground could be found; the natives black, with short hair, but others appeared of a more tawny colour, with canoes of a different shape. Among the Islands in sight to the northward, four small ones continually smoked. On approaching the mainland, the natives, whom he calls real Papoos, came off, " a wild, strange, and ridiculous people, active as monkeys, having black curled hair, rings in their ears and noses, and necklaces of hog's tusks." They had all some personal defect; one was blind, another had a great leg, a third a swelled arm, which made Schouten conclude that this part of the country was unhealthy, in which he was more confirmed by observing their houses built upon stakes eight or nine feet from the ground. At the two little Islands of Moa and Insou, on the north-east coast, the friendly natives supplied them with abundance of cocoa nuts. At 28 leagues from Moa, Schouten fell in with a group of fourteen small Islands covered with wood, but apparently uninhabited; but sailing to the northward, they were followed by six large canoes, the people in them armed with javelins. Those in some canoes from

another Island were of a tawny complexion, had long curly hair, and appeared, by their persons and language, to be a different race from the natives of Papua; they had rings of coloured glass, yellow beads, and vessels of porcelain, which were regarded as "evidences of their having communication with the East Indies." Schouten's Island is the largest of this group. Tasman visited all these islands, and the coast of New Guinea, in 1643, and obtained vast numbers of cocoa nuts and bananas from the friendly natives of Moa and Insou. Tasman made no discoveries in this part of his voyage.

Our countryman Dampier saw the coast in 1699, but did not land; the natives came off to his ship, and he speaks in admiration of their large and picturesque *proas*. He discovered, however, a Strait unknown before, which divides New Guinea from New Britain, and is now called after his name. Bougainville was less fortunate, when, in 1768, he touched on the coast of what he considered to be a separate Island, and to which he gave the name of Louisiade; there is, however, some reason to believe that it is a continuation of New Guinea. D'Entrecasteaux, in 1792, passed along the northern coast of Louisiade, and through Dampier's Strait, but left the point of its identity with, or separation from, New Guinea undecided.

Sonnerat published "*A Voyage to New Guinea*," though he evidently never was there, but describes the natives and productions from what he saw, and what he could collect at the island of Gibby, to the eastward of Gillolo.

Forrest, in 1775, anchored in the Bay of Dory, on the northern extremity of New Guinea, and collected some information respecting the inhabitants from a Mahomedan Hadji, who accompanied him. Captain Cook, also, in his first voyage in 1770, made the coast in about $6\frac{1}{2}^0$ south latitude, a little to the northward of Cape Valscher, but did not bring his ship to anchor, on account of the hostility of the natives. A party landed near a grove of cocoa-nut trees, and not far from it found plantain, and the bread-fruit tree. The breeze from the trees and shrubs is said to have been charged with a fragrance not unlike that of gum *benjamin*. Three Indians rushed out of the wood with a hideous shout, ran towards the party, the foremost throwing something out of his hand which burnt like gunpowder, the other two hurling their lances at the same time. Before they reached the pinnace, from sixty to a hundred had collected, all stark naked; their appearance as to stature, colour, and crisped hair, resembling that of the New Hollanders. They let off fires by four or five at a time, but for what purpose could not be imagined. These fires appeared to be discharged from a piece of stick, probably a hollow cane; and the fire and smoke exactly resembled those of a musket, but without any report. Those who were on board ship, at a distance, concluded they had fire-arms, and even those in the boat might have supposed them firing volleys, had they not been so near as to ascertain that there was no report. Torres had observed something of the same kind, in about 4^0 south latitude on the same coast, where, he says, the inhabitants were black, but better clothed than those southward; that among the weapons used by them were hollow bamboo sticks, which they filled with lime, and by throwing it out, endeavoured to blind their enemies: this explanation, however, does not account for the *fire*. Forrest says, that the Chinese, from Tidore, trade with Papua, under Dutch colours; perhaps, therefore, gunpowder may be one of the articles carried by them in exchange for the slaves, ambergrease, sea-slugs (biche de mer), tortoise-shell, loories, birds of paradise, &c. which they carry back to China.

Australasia.

General View of Papua. If we suppose the Louisiade of Bougainville to be connected with New Guinea, this Island extends in a south-east by east direction from the Cape, absurdly called Good Hope, nearly under the equator, to Cape Deliverance, in $11\frac{1}{2}^0$ south, being in length about 1400, and medial breadth about 150 geographical miles. The accounts of all the navigators who have touched on the different parts of its coast, describe it as a rich and magnificent country, containing, in all human probability, from its situation and appearance, all the valuable vegetable products of the Moluccas and the several Asiatic Islands. Forrest found the nutmeg-tree on Manaswary Island in the Bay of Dory; and he learned that a people in the interior, called *Haraforas*, cultivate the ground, and bring their produce down to the sea-coast; that they are very poor, and some of them have long hair, and that they live in trees, which they ascend by cutting notches in them. The people of New Guinea, in many parts of the coast, live in huts, or cabins placed on stages that are erected on poles, commonly in the water; probably as a protection against snakes and other venomous creatures; though Forrest seems to think against the Haraforas. On these stages they haul up their proas or canoes. These people are invariably described as being hideously ugly; their large eyes, flat noses, thick lips, woolly hair, and black shining skin, denote almost to a certainty their African origin, and their affinity with the natives of New Holland; but the difference of language, and the want of all the useful productions on the latter, which abound on New Guinea, induced Captain Cook to conclude, that there is no intercourse between the two people. The Papuans increase their natural deformity by passing bones or pieces of stick through the cartilage of the nose, and frizzing out their curly locks like a mop, sometimes to the enormous circumference of three feet. They appear, however, to be one degree farther removed from savage life than the New Hollanders, having permanent houses, and both men and women wearing wrappers round the waist, which are among the articles brought to them by the Chinese and Malays.

Natives.

Animals. The only quadrupeds that are known to exist on this large Island are dogs, rats, and wild hogs; but the feathered race are of great beauty and infinite variety. New Guinea is the native country of those singular and matchless beauties, the *birds of paradise*, which were once thought to have no legs, but always on the wing, and known by the name of *passaros da sol*, birds of the sun. They are said to migrate in large flocks, in the dry Monsoon, to the Islands of Arroo, and other Islands to the west and north-west of New Guinea. The great crown pigeon, parrots, loories, and minas, are natives of Papua.

Australasia.

The whole of this great country is indented with deep bays on every side, some of which nearly intersect the Island; and the coast is surrounded on every side with a multitude of small Islands, all peopled with the same description of Blacks, excepting those already mentioned on the north-west, near the equator, most of which are under the government of Mahometan Malays, with whom both the Dutch and Chinese have long kept up a considerable intercourse.

New Britain, New Ireland, and neighbouring Islands.

IV. There can be little doubt that this extensive range of Islands was partially seen by Le Maire and Schouten in 1616, who, after discovering the Groene Island and the Marquen Islands, steered along the northern coast of New Ireland, as did Tasman also in 1642. Dampier, however, first ascertained New Britain to be an Island distinct from New Guinea, by passing the strait which since has borne his name. He visited Port Montague on this Island, and speaks of the black natives resembling the Papuans, their dexterity in managing their canoes, their woody hills, fertile vales, and delightful rivulets. He also anchored in Slinger's Bay on New Ireland, which he conceived to be the same land with New Britain; but Carteret, in 1727, discovered and passed through a strait which separates them, and to which he gave the name of St George's Channel. The Admiralty Islands of Carteret, to the north-westward of New Britain, had previously been discovered by Schouten, and named *the Twenty-five Islands*. New Britain was seen by Roggewein in 1722, and by Bougainville in 1768.

Discovery.

D'Entrecasteaux, we believe, was the last navigator who passed along the north coast of New Britain, and through St George's Channel, which divides it from New Ireland, and from thence to the Admiralty Islands; and from his voyage, published by Rossel, together with Labillardiere and Carteret's, we shall extract a few gleanings.

General Description.

The extent of New Britain and Ireland is not exactly known, nor have they been sufficiently explored to enable geographers to lay them down with accuracy, or even to state what number of Islands the group consists of: one of considerable extent lies off the north-west end of New Ireland, which has been named New Hanover, and is itself surrounded by low woody Islands. The whole group occupies a space between $2\frac{1}{2}^{\circ}$ and 6° of south latitude, and 149° and 153° of east longitude, and may probably contain an area not less than 10,000 geographical miles.

Natives.

Carteret saw but few natives on the south coast of New Ireland, in passing through the strait, who showed marked signs of hostility, and were armed with lances headed with flint; they had also slings, and good fishing-tackle. They were black, and had woolly hair, but their lips, he says, were not thick, nor their noses flat; their cheeks were streaked with white, and their hair and beards were covered with a white powder; their canoes were long and narrow, and had generally outriggers; one of them measured 90 feet in length, and was formed out of a single tree. The two large Islands, and the whole group, in fact, were nearly covered with wood, and thick cocoa-nut groves skirted all the low parts of the coast. Labillardiere says that New Ireland produces nutmegs, and he also mentions a new species of the Areca palm, 108 feet high, the stem consisting of hard solid timber.

The natives of the Admiralty Islands, lying to the north-west, were found by Carteret to be less black than those of New Britain and Ireland, with agreeable countenances, not unlike Europeans; their hair was curly, smeared with oil and red ochre, and their bodies and faces painted with the same material; the glans penis was covered with the shell called the *Bulla ovum*, serving the same purpose as the wooden sheath of the Caffres in South Africa, whom, indeed, they seem to resemble as closely as the natives of New Guinea do those of the western coast of Africa. The women wear a bandage round the waist. The central Island is tolerably large, and of a beautiful appearance, clothed with the most luxuriant verdure, and cultivated to the very summit. Among the groves of cocoa-nut trees are numerous habitations, and the natives have evidently attained to a higher degree of civilization than their southern neighbours; they use earthen vessels, and chew the betel leaf with chunam or lime. This central Island is surrounded by nearly thirty small flat Islets of coral, and reefs in the various stages of their progress towards Islets.

Proceeding to the westward, and to the north-west, we meet with other little clusters of Islands,—as the Hermites, the Portland, the Echequier (chess-board), vulgarly called *Exchequer* Islands, all of which consist, like the Admiralty Archipelago, of a larger central Island surrounded by a chain of Islets and reefs, most of them covered with beautiful verdure. The natives of these groups, as they approach the equator, gradually assume a lighter colour and longer hair, till they lose entirely the negro character, and melt into that of Malays, and other Asiatic Islanders. (See *Schouten, Dampier, Carteret, Labillardiere, &c.*)

Solomon's Islands.

V. This archipelago of Islands was one of the first discoveries of the Spaniards in Australasia, though the credit of it is given to Alonso de Mendana, who was sent on an expedition of discovery in 1567 from Callao by the Viceroy of Peru. He anchored in a port on the Island of Santa Ysabel, to which he gave the name of Porta de la Estrella, and he also built a brigantine to make farther discoveries, in which she was particularly successful, having fallen in with thirty-three Islands in number, "of very fine prospect." Many of them were of considerable size, to which they gave particular names, as *Galera, Buonavista, Florida, San German, Guadalcanar, San Christoval, Santa Catarina*, and *Santa Ana*. Guadalcanar, however, was the most attractive, having a port which they named *De la Cruz*, and a river which they called *Galego*. Of this Island Mendana took possession for the King of Spain. When the voyage was published, the name of Solomon's Islands was given to the group, "to the end that the Spaniards, supposing them to be those Isles from whence Solomon fetched gold to adorn the temple at Jerusalem, might be the more desirous to go and inhabit

Australasia. the same;" but it has been said that Mendana's advice was, that they should not be colonized, "that the English, or others, who pass the Strait of Magelhanes to go to the Moluccas, might have no succour there, but such as they get from the Indians." The truth, however, is, that Mendana, on a second voyage for the discovery of the Solomon Islands, returned without being able to find them, which gave occasion to the remark, that, "what Mendana discovered in his first voyage, he lost in his second." He discovered, however, in this second voyage, the great Island of Santa Cruz, which is situated at the south-east extremity of Solomon's Islands, and may very fairly be considered as one of the group. This Island, which has an excellent harbour, *La Graciosa*, was first revisited by Carteret, in 1767, after Mendana's discovery, who changed its name to that of Egmont, and made it the principal Island of a group which he called Queen Charlotte's Islands. Here Mendana died, and Quiros succeeded to the command; but the search for Solomon's Islands was abandoned when they were not more than 40 leagues from Christoval. It is a singular fact, that Solomon's Islands, whose name was sufficient to tempt adventurers, were lost to Europeans for two centuries after their discovery, and that we know at present little, if any, more than Mendana gave to the world after his first voyage. They were revisited by Bougainville in 1768; by M. Surville in 1769, on a voyage from Pondicherry of mercantile speculation, and who, from a ridiculous mistake, called them the Archipelago of the *Arsacides*, to mark the natives as *assassins;* and by Lieutenant Shortland, of the British navy, in 1788, who chose to call them New Georgia; and frequently since that time by various British and French navigators;—still the little we know of them is from Mendana.

Natives. Santa Ysabel, he says, was inhabited by people who had the complexion of mulattos, with curly hair, with little covering to their bodies, who worshipped serpents, toads, and such like creatures; their food cocoa-nuts and roots; and it was believed that they eat human flesh, "for the chief sent to the general a present of a quarter of a boy with the hand and arm." Buonavista is twelve leagues in extent, very fertile, well peopled, the natives living in regular villages or towns. On Florida, twenty-five leagues in circuit, the natives dyed their hair red, collected together at the sound of conch-shells, and eat human flesh. Sesarga was well inhabited, produced plenty of yams and bread-fruit, and here the Spaniards saw hogs. In the midst of the Island was a volcano, continually emitting smoke. They saw bats which measured five feet between the tips of the wings. At Guadalcanar they received in barter two hens and a cock, the first fowls that had been seen. At San Christoval, the natives were very numerous, and drew up to give battle to the Spaniards, their arms being darts, clubs, bows and arrows; but they were dispersed by the fire of the muskets, which killed one Indian, and wounded others. In the neighbouring village was found a quantity of cocoa-nuts and almonds, sufficient to have loaded a ship. Santa Ana was well peopled and fertile. It has a good port on the east side, where the Spaniards were attacked by the natives, who wounded three of the invaders, and one dart pierced through the target and arm of the Spanish commanding officer; the blacks had boughs on their heads, and bands round their waists. The Spaniards observed here hogs and fowls. Australasia.

VI. To the south-east of Solomon's Islands, and between the parallels of $14\frac{1}{2}^0$ and 20^0 south latitude, are found a number of Islands, some of very considerable magnitude, called the *New Hebrides*, or *Hebudes*. They were first discovered in 1606, by Pedro Fernandez de Quiros, who, with Luis Vaez de Torres, was sent by the King of Spain from Lima, with two ships and a zabra (launch) to establish a settlement at the Island Santa Cruz, and from thence to go in quest of the *Tierra Austral*, or southern continent. This voyage has been considered, and justly so, among the most celebrated undertaken by the Spaniards since the time of Magelhanes. In April 1606, they discovered an Island, to which they gave the name of *Santa Maria*, from whence they saw another Island to the southward, "so large," says Torres, "that we sailed for it." On the 2d May, they anchored in a bay, large enough to hold a thousand ships, to which they gave the appropriate name of *San Felipe y Santiago*. Quiros at once determined that he had now discovered the long-sought-for southern continent, and in this conviction named it the *Australia del Espiritu Santo*. Two rivers fell into the bay, one the Jordan, the other the Salvador. The surrounding country was beautiful, and is thus described by the historian of the voyage: "The banks of the rivers were covered with odoriferous flowers and plants, particularly orange flowers and sweet basil, the perfumes of which were wafted to the ships by the morning and evening breezes; and, at the early dawn was heard, from the neighbouring woods, the mixed melody of many different kinds of birds, some in appearance like nightingales, blackbirds, larks, and goldfinches. All the parts of the country in front of the sea were beautifully varied with fertile valleys, plains, winding rivers, and groves, which extend to the sides of green mountains." (*Torquemada*, as quoted in Burney's *Account of Discoveries in the South Sea*.) New Hebrides. Discovery.

Of this terrestrial paradise, which the Spaniards regarded as their own, it was intended to take immediate possession; they landed in great numbers; the Islanders were also numerous, became alarmed, made them presents, and signified a wish for them to return to their ships. They, however, landed from their boats, on which the chief drew a line on the ground with the end of his bow, and made signs that the Spaniards must not pass that boundary. It is said that Torres, to show his contempt of the idea of being restrained by barbarians, immediately passed the line. A battle ensued, in which the chief was killed, and all the rest fled into the woods. This rash act, however, was fatal to the views of the Spaniards, who never afterwards could prevail on the Islanders to have any friendly communication with them; and they left this country, after some ridicu-

Australasia. lous formalities of taking possession in the name of Philip III. and founding a city, dignified with the name of the *New Jerusalem*.

So anxious was Quiros of "adding the *Australia del Espiritu Santo* to the other possessions of the Spanish monarchy," that, after his return to Spain, he is said to have presented no less than fifty memorials to the King. One of these, which was printed at Seville, begins thus: "I, Captain Pedro Fernandez de Quiros, say, that, with this I have presented to your Majesty eight memorials relative to the settlement which ought to be made in *Australia Incognita*." In these memorials, he enumerates the many valuable productions of this supposed southern continent: cocoa-nuts, plantains, sugar-canes, yams, batatas, oranges, limes, papas, pumpkins, almonds, nutmegs, mace, ginger, and pepper, in great quantities; woods for "building any number of ships." The animals are hogs, goats, and dogs; fowls, and a variety of useful and beautiful birds; various good fish; and pearl oysters. The climate is described as so fine, and such a freshness in the air, that neither by labour, exposure to the sun, or rain, or dews, nor by intemperance, did any of the Spaniards fall sick; and among the natives many aged people were seen. They wear a covering round the middle: Torres says they are all black and naked. They are described by Quiros as corpulent and strong, cleanly, cheerful, sensible, and grateful; their houses stood on the ground, and not on poles, built of wood, and thatched. They weave nets, and make earthen vessels, have plantations inclosed with palisades, construct vessels which navigate to distant countries, and have places appropriated for burying the dead; and, he adds, as the last and decisive test of their progress in civilization, "they cut their hogs and make capons."

Description. This archipelago of Islands, like that of Solomon, was lost to the world for a century and a half, when Bougainville revisited them in 1768; but, except landing on the Isle of Lepers, did nothing more than discover that the land was not connected, but composed of Islands, which he called the *Great Cyclades;* which, on being more accurately and extensively explored by Cook, in 1774, underwent another change to that of New Hebrides, which they now bear in all our charts. According to the survey of our great navigator, they consist of *Tierra del Espiritu Santo*, the largest of the whole, *St Bartholomew*, *Mallicola*, *the Isle of Lepers*, *Aurora*, *Whitsuntide*, *Ambrym*, *Apee*, *Paoom*, *Three-hills*, *Sandwich*, *Montagu*, *Hinchinbrook*, *Shepherd's Isles*, *Erromango*, *Tanna*,

Natives. and *Immer*, *Annatom*, and *Erronan*. The two which are more particularly described, are Mallicolo and Tanna, the natives of which differ remarkably in their persons and language; those of the latter having curly but long hair, dark but not black, and without anything of the negro character in their features, which are regular and agreeable; their persons slender, active, and nimble. They found them hospitable, civil, and good-natured; but displayed a jealousy of their visitors seeing the interior of the Island, which could only be equalled in Japan or China. All the plantations were fenced, and laid out in a line: they consisted of sugar-canes, yams, plantains, bread-fruit, &c. The yams remarkably fine, one of which weighed fifty-six pounds, every ounce of which was good; and they had pigs and poultry. The juice of the cocoa-nut, and water, appeared to be their only beverage. Their arms were clubs, darts, lances, and bows and arrows. Their canoes, clumsily sewed together, had outriggers, and were worked by paddles and by sails. The men wore a wrapper round the loins, and the women a sort of petticoat reaching to the knee.

The natives of Mallicolo are called by Captain Cook "an ape-like nation;" the most ugly, ill-proportioned people he ever met with, and different from all others; diminutive in their persons, dark-coloured, with black hair, short and curly, but not so woolly as a negro's: they had long heads, flat faces, and monkey countenances, and a belt round the waist, pulled tight across the belly, made them look not unlike overgrown pismires. The women were equally ugly; the dress of both, in other respects, the same as that of Tanna, as were also the productions of the Island. Their houses were low, and covered with palm thatch. (See *Dalrymple*, *Burney*, *Cook*, &c.)

New Caledonia. VII. This large Island, surrounded with coral islets and reefs, was wholly unknown till Captain Cook, in 1774, fell in with the north-western extremity in steering south-west from Mallicolo, from which it is distant not more than about 80 leagues. He anchored within a small Island called Balabea, and opposite to the district Belade. The great Island extends between latitude 20° 5′ and 22° 30′ in the direction of north-west and south-east; about 250 miles long by 60 broad. (Description.) The land bears a great resemblance to that of New South Wales, and many of its natural productions appeared to be the same, but the natives were different. They are represented as a strong, robust, active, well-made people, courteous and friendly, and not in the least addicted to pilfering, in which respect they differ from every other tribe of Australasia. They are nearly of the same (Natives.) colour as the natives of Tanna, and appeared to be a mixed race between that people and those of the Friendly Isles, or of Tanna and New Zealand; their language being a mixture of them all. Of the same disposition as the natives of the Friendly Islands, they were found to excel them in affability and honesty; and the women, like those of Tanna, were more chaste than the females of the more eastern Islands, not one of the ship's company having been able to obtain the least favour from any one of them. They wear a petticoat of the filaments of the plantain tree, "at least six or eight inches thick, but not one inch longer than necessary for the use designed." They paint and puncture their bodies, and wear ear-rings, and necklaces, and bracelets, of tortoise and other shells. Both men and women have good features and agreeable countenances, and some of the men measured in height six feet four inches. Their hair is frizzled out like a mop, is very black, coarse, and strong, different from that of a negro. The ruff mop-heads make use of "scratchers," composed of a number of sticks of hard wood, about the thickness of knitting-needles, fastened together at one

Australasia.

end like a sort of comb; the women have their hair cropped short. The men wear a wrapper round the loins, made of the bark of a tree. Their houses resemble bee-hives, with peaked roofs, entered by a hole just big enough to admit a man bent double. The sides are of spars and reeds, and both these and the roof well thatched with dry grass. They boil their roots and fish in earthen jars. They have nets made of plantain fibres, and the sails of their canoes are of the same material. These vessels consist of two trees fixed together by a platform. They have plantations of sugar-canes, plantains, bread-fruit, and cocoa-nut, but none of them very productive. The whole appearance of the country, indeed, is described as unable to support many inhabitants. The greater part of the visible surface consists of barren rocky mountains; and though the plains and valleys appeared to be fertile, Captain Cook was of opinion that "nature has been less bountiful to it than to any other tropical Island we know in this sea."

D'Entrecasteaux passed the opposite extremity of New Caledonia in 1792, when on his search after the unfortunate La Pérouse, but was prevented by a barrier reef of coral from approaching the coast; and, in the following year, he visited Balade on the north-west. The account of the inhabitants, as given by Rossel and Labillardiere, differs altogether from that of Cook. Instead of finding them friendly, honest, and inoffensive, they are described as the worst of cannibals; not only eating the flesh of their enemies, but feeding on little children; ferocious in their dispositions, the most audacious thieves, and the women the most shameless prostitutes. But their own account of their transactions there, the confidence with which they straggled over the country, and the readiness of the savages to serve them, by no means warrant the bad character they have thought fit to give them; and they had no more proof of their being cannibals, than they had for accusing the people of Van Dieman's Land of the same practices, because the Surgeon Major mistook the bone of a kangaroo for that of a young girl. They appear to have endeavoured, by signs, to extort a confession to this effect from the poor savages, who, on their part, were also persuaded that the French were the real cannibals. The charge brought against the women is grounded solely on two young girls having been prevailed on by some of the crew to expose what decency requires to be concealed, in return for some pieces of cloth or iron. Labillardiere thinks the inhabitants, as well as the vegetable productions, resemble those of Van Dieman's Land. There was no want of different kinds of esculent plants, though a great scarcity prevailed from drought, or other cause, when they arrived. The young shoots of the *Hybiscus tiliaceus*, the fruit of the *Cordia sebestina*, the *Dolichos tuberosus*, *Helianthus tuberosus*, *Arum esculentum*, and *Macrorrhizon*, *Hypoxis*, *Aleurites*, figs, oranges, plantains, sugar-canes, cocoa-nuts, and the bread-fruit,—all afforded them articles of food. Yet Labillardiere says they eat steatite, and that he saw one man devour a piece of this stone as large as his two fists. They also eat a species of spider. They had lost the hogs which Cook left them, but some half dozen of cocks and hens were seen by the French. (See *Cook*, *Labillardiere*, &c.)

Australasia.

New Zealand.

VIII. Though these Islands geographically belong to Australasia, the natives are, in their physical character and language, Polynesians. They were first discovered on the 13th December 1642, by Abel Jansen Tasman, on his voyage of discovery from the Mauritius; and, on the 18th, the Heemskirk yacht, and the fly-boat Zeehaan, came to anchor in a bay to which they afterwards gave the name of Moordenaar's or Murderer's Bay, and to the Island that of *Staaten Land*, in honour of the States General, and in the possibility that it might join the Staaten Land to the east of the Tierra del Fuego. "It is a fine country," says Tasman, "and we hope it is part of the *unknown South Continent*." The expedition of Hendrik Brower to Chili the following year, cut off the latter Staaten Land from any continental connection, and the name of the former was then changed to that of *New Zealand*.

Discovery.

On the 19th, a boat with 13 natives came within a stone's throw of the Heemskirk. The language in which they hailed was unlike that of the Solomon's Islands, of which Tasman had a vocabulary. Their vessel consisted of two narrow canoes, joined together by boards, on which the people sat; their paddles, about a fathom long, pointed at the end; their clothing appeared of matts or cotton, but their breasts were naked. They invited them to come on board, but in vain. The ships, however, were moved nearer in shore, upon which seven double vessels came off. A boat, being dispatched from one ship to the other, was previously attacked. Three men belonging to the Zeehaan were killed, and one mortally wounded; one of the killed was dragged into the canoes. After this, despairing of getting water or provisions, they weighed and set sail, twenty-two of the native boats following them, eleven of which were full of people. The ships fired, and the canoes returned to the shore.

The next visitor, at the distant period of 127 years, was Captain Surville, who, in 1769, put into a bay on the north-eastern extremity, and gave it the name of Lauriston Bay. In the same year, Lieutenant (afterwards Captain) Cook, of the Endeavour, made the land on the 6th October 1769, the enormous height of which became the subject of much conversation; and the general opinion was, that they had now discovered the *Terra Australis incognita*. This voyage, however, and the circumnavigation of the Islands of New Zealand, entirely subverted the theory of a great southern continent. In 1772, Captains Marion du Fresne and Crozet put into the Bay of Isles, where the former, and some of the crew, were murdered by the natives. In March 1773, Captain Cook in the Resolution, with Captain Furneaux in the Adventure, revisited New Zealand, where the latter had a whole boat's crew, with a midshipman, murdered by the inhabitants. In 1776 and 1777, a third visit was made to these Islands by Captain Cook. In these several visits, accompanied as he was with men well versed in every branch of natural knowledge, there will be found in the *Voyages* of Cook and Forster every species of information that

Australasia.

the ferocious disposition of the inhabitants made it practicable to collect.

Description.

The two great Islands of New Zealand extend between latitude 34° and 48° south, longitude 181° and 194° east; that to the northward called Eaheinomawe, is about 400 G. miles long by 90 medial breadth; the name of the southern Island is Tavaipoenammoo, is about 450 G. miles long by 95 broad; the former has a rich and fertile soil, well clothed with trees, some of them more than 20 feet in girt, and 90 feet high, without a branch. Some of them resembled spruce, and were " large enough for the mainmast of a 50 gun ship." The highest hills were covered with forests, the valleys with grass and shrubbery, and the plains were well irrigated with rills of clear water. The southern Island is very mountainous; one peak, resembling that of Teneriffe, was estimated by Forster, but without sufficient data, at 14,000 feet of height; it was covered with snow in the middle of January. Both as to appearance and temperature, they may be considered as the British Isles of Australasia. Fahrenheit's thermometer in February was never higher than 66°, and was not lower in June than 48°.

A great part of the western side of those Islands had, however, a desolate and inhospitable appearance; exhibiting ranges of yellow sandstone, or white sand hills, with scarcely a blade of verdure. It is worthy of remark, that this extraordinary difference prevails between the two coasts of South Africa, the two coasts of New Holland, and the two coasts of Van Dieman's Land.

Natives.

The natives are stout, well limbed, and muscular, vigorous and active, excelling in manual dexterity; their countenances intelligent and expressive, of an olive complexion, but not darker than a Spaniard. In the appearance of the women, there is not much feminine delicacy; but on Cook's first visit, they found them more modest and decent in their behaviour, than in any of the islanders they had met with; they were covered from the shoulders to the ankles with a sort of netted cloth, made of the split leaves of the flax plant (*Phormium tenax*), the ends hanging down like fringe. A party once came upon some women by surprise, as they were fishing, naked, for lobsters, and " the chaste Diana, with her nymphs, could not have discovered more confusion and distress at the sight of Actæon, than these women expressed upon our approach." On the third visit, however, they had got rid of all their modesty, and a rusty nail was sufficient to purchase the last favour.

The black hair of the men is bound in a knot on the top of the head; that of the women is cropped; both sexes anoint their hair with rancid oil, and smear their bodies with grease and red ochre. The faces of the old men are covered with large furrowed black marks, generally spiral lines, and have a horrible appearance. The women wear in their ears pieces of cloth, feathers, sticks, bones, &c. and bracelets and anklets of bone, teeth, shells, &c. Captain Cook did not observe any appearance of disease, or bodily complaint, or eruption on the skin, or marks of any; and the most severe wounds healed most rapidly. Very old men, without hair or teeth, showed no signs of decrepitude, and were full of cheerfulness and vivacity. They are mild, gentle, and affectionate towards each other, but ferocious and implacable towards their enemies; and it unfortunately happens, that the little societies into which they appear to be divided, are in an almost perpetual state of hostility, which makes it necessary for them to dwell in happahs or villages, fortified with embankments, ditches, and pallisadoes. They give no quarter, and feast with apparent relish on the bodies of their enemies, which they cut up and broil in holes dug in the earth; they suck out the brains, and preserve the skulls as trophies. They made no hesitation in devouring human flesh in presence of the English officers, and their provision baskets had generally the head or a limb of a human subject.

Australasia.

The only quadrupeds on the Islands are dogs, small and ugly, and rats, the former of which they eat, and with their skins, cut into strips, they adorn their clothing; but their principal food consists of fish, and the bruised roots of fern. They cultivate, however, and with great neatness, sweet potatoes, eddas, and gourds, all planted in regular rows; and Cook observed, near the villages, both privies and dunghills. Their houses have a ridge-pole to the roof, which, with the sides, are built of sticks and grass, and lined with bark; they sleep on the floors covered with straw; and the furniture consists of a chest to hold their tools, clothes, arms, and feathers, provision baskets, and gourds to hold water, which is their only beverage; the New Zealanders being among the very few people, civilized or savage, who are ignorant of the means of intoxication.

Their double canoes, or whale boats, are admirably constructed with planks from 60 to 70 feet in length, and their prows and sterns are tastefully and curiously carved and ornamented, all of which is performed by adzes and axes of a hard black stone, or green talc or jade, and with chisels of human bone or jasper. Of these materials also are their offensive weapons made: these are lances fourteen feet long, sharp at both ends, of hard wood, neatly carved; and a battle axe of jade or bone about a foot long. Their war canoes carry from 60 to 70 men each; they keep exact time with their paddles, singing, with great vociferation and distorted features, their savage war song, when bound on any hostile expedition. Their war dances are conducted in the same furious and extravagant style; the only musical instrument, if it can be called one, is a triton shell, which sounds like a cow's horn.

They have, however, a taste for music, and the women are said to sing in a soft, slow, and mournful cadence, making use of semitones. When their husbands are slain in battle, they cut their legs, arms, and faces, with bone or sharp shells, and few of them that do not wear scars on their bodies as testimonials of their affection and sorrow for their deceased friends.

The natives of New Zealand exhibit a strange mixture of civilized and savage life. It was hoped from the state of their cultivated grounds, of which several hundred acres were seen, that presents of hogs, kids, and poultry, would have been most acceptable, and considerable numbers were left with them

Australasia.

on the first and second visits of Captain Cook; but, excepting the cocks and hens, which had bred plentifully, and flew about wild in the woods, the others had been wantonly destroyed. In 1791, Vancouver touched at Dusky Bay, and remained there for some time, examining the bays and creeks in the neighbourhood; but they did not see one human being. And, in 1793, D'Entrecasteaux passed between the Three King's Island, and Cape Maria Van Dieman, but had no other communication with the natives but in their canoes. Unlike in every respect to the Otaheitans, they have evidently a common origin; their language not differing more than the language of the two New Zealand Islands from each other. The few notions they have of superior beings also accord with those of Otaheite. (See *Cook's Voyages.*)

A missionary of the name of Marsden, from merely seeing some New Zealanders in New South Wales, had the hardihood to accuse Captain Cook of having drawn "a false picture of the New Zealanders." He undoubtedly thought so, and went to the Islands with a view of converting the natives to Christianity. He soon, however, abandoned this "noble race of men," as he calls them, being unable, by his own account, "to lay the first stone;" consoling himself for his disappointment by the reflection that "the pious Israelites could not build the walls of Jerusalem without holding the sword in one hand and the trowel in the other." Captain Cook's accuracy is too well established to be shaken by such authority. The following horrible transaction proves how well he described the character of these cannibals. In December 1809, the ship Boyd, from Port Jackson, was at Wang-arrooa, in the Bay of Islands, and admitted, without due caution, too large a number of natives on board, when the crew were suddenly attacked, overpowered, and slaughtered. Captain Alexander Berry of the ship Edinburgh Castle, being on the coast, was soon after apprised of this horrible event; and, proceeding to the bay, found the remains of the Boyd, which had been burned by the savages. On landing, he discovered that the massacre had been directed by Tippahee, the old chief, who had been so much caressed at Sydney. The bones of the unfortunate men lay scattered on the ground, where their bodies had been devoured by the savages. Sixteen were murdered and cut up on the deck of the vessel; five others, who had fled for safety upon the yards, were told by the old cannibal, that if they would come down their lives should be spared, which, after some hesitation, they consented to do. They were sent on shore; and in five minutes after, their dead bodies lay on the beach. The only survivors which Captain Berry contrived to save, were a woman, two children, and a boy. Well might Captain Berry conclude the narrative of his horrid murder by an admonition, "Let no man trust a New Zealander."

To the eastward of New Zealand is an Island of considerable extent and well peopled, discovered by Mr Broughton in 1791, when on a voyage round the world with Vancouver. He called it Chatham Island; the people and its productions the same as those of New Zealand. (See *Vancouver's Voy.*)

It may be proper here to notice a recent discovery of a group of Islands directly south of the south cape of Tavai Poenammoo, one of the New Zealands, named *Lord Auckland's Group*, by the discoverer, Mr Bristow, master of a South Sea Whaler, in gratitude to the nobleman whose name they bear, for having, when a boy, procured him admission into the school of Greenwich Hospital. This group, seven in number, were first seen on the 10th August 1806; and, on the 20th October 1807, Captain Bristow came to anchor with his ship, the Sarah, in a fine harbour on the largest Island, which he called *Enderby*, and to the harbour he gave the quaint one of *Sarah's Bosom.* They are situated in lat. 50° 40′ south, and long. 166° 35′ east. Wood and water being plentiful, and easily procured, they are represented as holding out, in this desolate and remote region, considerable advantages to the southern whale fishery. The climate, however, is unusually severe, and the weather tempestuous. In the middle of summer (December), every day was attended with snow, sleet, or rain. Yet this severity of climate appeared to make no unfavourable impression on the vegetable productions, as the woods were covered with verdure so early in the spring as October. He observed four kinds of timber trees, the principal of which was mangrove (quæry?) growing to the height of 30 or 40 feet; but the trunks were so twisted and turned by the violent winds, that it was difficult to find a straight piece of ten feet in length. There was no want of shrubby and herbaceous plants; there were neither men nor quadrupeds of any kind, but seals, sea-elephants, and sea-fowl, in great plenty. The woods abounded with a great variety of singing birds, with sweet melodious notes, and among them was a species of lark; wild-ducks, seals, and snipes were plentiful, and he caught a kind of rock-cod with the hook and line.

Australasia.

Lord Auckland's group of Islands.

To the southward of the group, another small Island was discovered in 1811, to which was given the name of Campbell's Island; and to the south-west of them, Macquarrie's Islands, in latitude 55° south, and longitude 160° east. Several other Islands are scattered about those of New Zealand; Chatham Island to the eastward of it, and a group of small ones near it, seen by the Cornwallis in 1807; Bounty Island to the south-east; and to the southward of the latter, a little Island, which, from its position with regard to England, has been named *Antipodes* Island. (Bristow's *MS. Letter.*)

Kerguelen's Land.

IX. Between the parallels of 48½° and 50° south, and longitude 69° east, lies the barren and uninhabited Land of Kerguelen; so named from the French officer who first discovered it in 1772, and who, on a second visit in 1773, discovered some small Islands near it, but on neither occasion was able once to bring his ships to an anchor upon any part of the coast. Captain Cook was more fortunate. He had heard of Kerguelen's discovery at the Cape of Good Hope, and wondered he should not have seen this land when he passed it so closely in 1770. In 1776, however, he fell in with these Islands; and, as no account of Kerguelen's voyage had been made public, he gave new names to each Island. Speaking of the main Island—"I should," says Cook, "from its sterility, with

Discovery.

Australasia. great propriety call it 'the *Island of Desolation*,' but that I would not rob M. de Kerguelen of the honour of its bearing his name." He changed, however, the "*Baie de L'Oiseau*" of the French, where they had landed in a boat, and lodged a piece of parchment in a bottle, into *Christmas Harbour*; and called a round high rock "Bligh's Cap," which had been named by M. de Kerguelen the "Isle of Rendezvous;"—although, says Cook, "I know nothing that can rendezvous about it but fowls of the air; for it is certainly inaccessible to any other animal." Kerguelen thought he had discovered the *Terra Australis Incognita*, but Cook soon determined that it was of no great extent.

The hills were but of a moderate height, and yet, in the middle of summer, were covered with snow; not a shrub was found on this Island, and not more than 17 or 18 different plants, one half of which were either mosses or grasses; the chief verdure was occasioned by one plant not unlike a saxifrage, spreading in tufts, and forming a surface of a pretty extensive texture, over a kind of bog or rotten turf; the highest plant resembled a small cabbage, when shot into seed, and was about two feet high. No land animals were met with, but great plenty of the ursine seal (*Phoca ursina*). Penguins were very abundant, as were also shags, cormorants, albatrosses, gulls, ducks, petterels, and sea swallows. A few fish of the size of a haddock were taken with the line, and the only shell-fish were a few limpets and muscles.

The steep cliffs towards the sea are rent from the top downwards, but whether by rains, frost, or earthquakes, could not be determined; the productions of the hills were composed chiefly of a dark blue and pretty hard stone, intermixed with small particles of glimmer or quartz; lumps of coloured sandstone, and of semitransparent quartz, are also common; nothing appeared like an ore, or metal of any kind. (Cook's *Third Voyage*, Vol. I.)

St Paul and Amsterdam.

X. These small uninhabited Islands are interesting only in a geological point of view. Situated in the midst of the great Indian Ocean, at the distance of 2000 miles from the nearest land, and removed but 18 or 20 miles from each other, they have no common point of resemblance: the one being the product of a volcanic eruption, scarcely yet cooled, with a few mosses and grasses on its surface; the other composed of horizontal and parallel strata of rock, covered with frutescent plants; an appearance which led the scientific gentlemen in D'Entrecasteaux's expedition to conclude, that an organization so regular could not proceed from a volcanic origin. A French seal-catcher, from the neighbouring island, had set fire to the shrubbery, which continued to burn when the navigators passed the Island; and imagining that they saw pits of smoke issuing from the crevices between the strata, some of them were disposed to consider this circumstance as infallible indications of subterranean fire. Perron, the seal-catcher above mentioned, with the gentlemen of Lord Macartney's embassy, who explored the southernmost Island, Amsterdam, says that the shores of St Paul's abounded with pumice stone, but the presence of this light material is by no means an infallible criterion of a Australasia. proximate eruption.

Of the recent creation of Amsterdam there can be little doubt; indeed, it is scarcely yet cooled, and is altered considerably since its first discovery by Vlaming in 1696. From every part of the sloping sides of the crater, which is nearly 1000 yards in diameter, and into which the sea has forced its way, either smoke, or hot water, or hot mud, are seen to issue; and everywhere is felt a tremulous motion, and a noise heard like that of boiling water. In many parts of the crater, in the centre of which the water is 174 feet deep, the sea-water is tepid from the hot springs below; and numbers of these springs are found on the margin, below the high water mark, of various temperatures, from 100° to the boiling point. One very copious spring, slightly chalybeate, issues, in a copious stream, into the crater, nearly on a level with the lowest state of the tide. These springs cannot possibly descend from the summit of the Island, the highest parts of which are the edges of the crater, about 600 feet, and the whole area of the Island is not more than eight square miles; a surface totally inadequate to collect and condense the clouds, so as to produce these permanent springs. Why some modern geologists, and among them M. de Humboldt, should doubt of sea-water being converted into steam, and undergoing the process of distillation by subterranean fire, we are at a loss to know, or in what other manner they would account for such large and permanent streams of fresh water, so situated as those are of Amsterdam Island.

Another singularity which this Island presents, is in its mosses and grasses, which are all European; to these may be added the *Sonchus oleracea*, or sow thistle; and the *Apium petrosilenum*, or parsley; and the *common Lycopodium*, or club-moss, which grows luxuriantly on the bleak heaths of North Britain, seems to thrive equally well on the boggy soil of Amsterdam, heated, at the depth of a foot below the surface, to the temperature of 186° of Fahrenheit's scale.

The crater abounds with an excellent perch, of a reddish colour, which is easily caught with the hook, and may be dropped at once into one of the hot springs on the margin, and boiled alive; and so caught and dressed, we are told, it affords an excellent repast. The bar across the mouth of the crater is represented as one mass of cray-fish; and in the sea, outside the bar, are vast multitudes of whales, grampusses, porpoises, seals, and sea lions, so as to be dangerous for boats to pass. It was the same in Vlaming's time, who "found the sea so full of seals and sea lions, that they were obliged to kill them to get a passage through; when they steered from the shore, there was also an astonishing number of fish."

Numerous Reefs and Islets of Coral scattered over the Australasian Sea.

XI. From the volcanic Island of Amsterdam, we must now take a glance of those innumerable low Islands and reefs of rocks which are scattered over the greater part of the Australasian Sea, to the eastward and northward of New Holland, and which are produced by a different operation of nature to that which lifted up Amsterdam—less violent, indeed, and

with less eclat than the latter, but equally, if not more firmly, established on the solid foundations of the deep abyss. A volcanic Island not unfrequently breaks down its supporters, and sinks back into the cavity out of which it was hurled, as was recently the case with the Sabrina Island, near St Michael's; but the Island of coral, created by slow and imperceptible degrees, hardens with time, and becomes one solid mass from the summit to the base.

We know very little, as yet, of the nature of the marine polypi that construct these wonderful fabrics, but we cannot be blind to the effects of their operations. Throughout the whole range of the Polynesian and Australasian Islands, there is scarcely a league of sea unoccupied by a coral reef or a coral Island; the former springing up to the surface of the water perpendicularly from the fathomless bottom, "deeper than did ever plummet sound," and the latter in various stages, from the low and naked rock, with the water rippling over it, to an uninterrupted forest of tall trees. "I have seen," says Dalrymple, in his *Inquiry into the Formation of Islands*, "the coral banks in all their stages; some in deep water; others with a few rocks appearing above the surface; some just formed into Islands, without the least appearance of vegetation; others with a few weeds on the highest part; and lastly, such as are covered with large timber, with a bottomless sea, at a pistol-shot distance." In fact, as soon as the edge of the reef is high enough to lay hold of the floating sea-wreck, or for a bird to perch upon, the Island may be said to commence. The dung of birds, feathers, wreck of all kinds, cocoa-nuts floating with the young plant out of the shell, are the first rudiments of the new Island. With Islands thus formed, and others in the several stages of their progressive creation, Torres' Strait is nearly choked up; and Captain Flinders mentions one Island in it covered with the *Casuarina*, and a variety of other trees and shrubs which give food to paroquets, pigeons, and other birds, to whose ancestors, it is probable, the Island was originally indebted for this vegetation. The time will come,—it may be ten thousand or ten millions of years, but come it must,—when New Holland, and New Guinea, and all the little groups of islets and reefs to the north and northwest of them, will either be united into one great continent, or be separated only with deep channels, in which the strength and velocity of the tide may obstruct the silent and unobserved agency of these insignificant but most efficacious labourers.

A barrier reef of coral runs along the whole of the eastern coast of New Holland, "among which," says Captain Flinders, "we sought fourteen days, and sailed more than 500 miles, before a passage could be found through them out to sea." Captain Flinders paid some attention to the structure of these reefs, on one of which he suffered shipwreck. Having landed on one of these new creations, he says, "We had wheat sheaves, mushrooms, stag's horns, cabbage leaves, and a variety of other forms, glowing under water, with vivid tints of every shade betwixt green, purple, brown, and white." "It seems to me," he adds, "that when the animalcules, which form the coral at the bottom of the ocean, cease to live, their structures adhere to each other, by virtue either of the glutinous remains within, or of some property in salt-water; and the interstices being gradually filled up with sand and broken pieces of coral washed by the sea, which also adhere, a mass of rock is at length formed. Future races of these animalcules erect their habitations upon the rising bank, and die in their turn, to increase, but principally to elevate this monument of their wonderful labours." He says, that they not only work perpendicularly, but that this barrier wall is the highest part, and generally exposed to the open sea, and that the infant colonies find shelter within it. A bank is thus gradually formed, which is not long in being visited by sea-birds; salt-plants take root upon it, and a soil begins to be formed; a cocoa-nut, or the drupe of a pandanus, is thrown on shore; land-birds visit it, and deposit the seeds of shrubs and trees; every high tide and gale of wind add something to the bank; the form of an Island is gradually assumed; and last of all comes man to take possession.

If we should imagine one of these immense coral reefs to be lifted up by a submarine volcano, and converted into an insular or continental ridge of hills, such a ridge would exhibit most of the phenomena that are met with in hills of limestone.

It is worthy of remark, that, in this great division of the globe, fully equal in extent to that of Europe, there is no quadruped larger than the kangaroo; that there is none of a ferocious character, and, in many of the Islands, none of any description. Man only in Australasia is an animal of prey; and more ferocious than the lynx, the leopard, or the hyena, he devours his own species, in countries too where nature has done every thing for his comfort and subsistence; the consequence is, that population is so much checked and thwarted, that the number of all the natives that have been seen on the coasts of all the Islands, from the first discovery to the present time, would not in the aggregate amount to 20,000 souls. The only hope of improvement must depend on the future colonization of these healthful and fertile regions of the globe by some European power. (K.)

AUSTRIA.

In strict geographical language, Austria is the name of only a large province in the south-east of Germany, but it is commonly used to denote the great empire, composed of the province in question, the kingdoms of Hungary and Bohemia, along with the provinces of Moravia, Carinthia, Styria, Tyrol, Transylvania, Galicia, Lombardy, Venice, and Dalmatia. This state has, of late years, undergone fre-

Austria. quent changes in point of territory and population. At the beginning of the French Revolution, the Austrian dominions were computed to contain a population of nearly 25,000,000. This number would have been materially increased in 1796, by the acquisition of Galicia and other parts of Poland, had not the cession of the Netherlands and Lombardy made a deduction, which kept it at nearly its original amount. The diminution, in fact, would have been considerable, had not the French tempted Austria to a separate peace in 1797, by seizing and transferring to her the territory of one of the oldest states in Europe,—the Republic of Venice. In the next war, the splendid successes of the campaign of 1799 at first promised to give back to Austria a portion of her lost territory; but the withdrawing of Russia from the coalition, and the fatal days of Marengo and Hohenlinden, led, in 1801, to a treaty which occasioned a further reduction of the imperial frontier. The third war, that of 1805, was equally short and disastrous, leading, after the overthrows at Ulm and Austerlitz, to the purchase of peace by the surrender of the Venetian territory, Tyrol, and other provinces, containing in all a population of nearly 3,000,000.

In 1809, the resistance of Spain prompted Austria once more to try her fortune in the field. Her army was numerous, and a large proportion of the French force was in the Peninsula; but Prussia remained neutral, and Russia took part, to a certain extent, against Austria. These circumstances enabled Bonaparte, at the head of a mixed force of French and Germans (of the Confederation of the Rhine), to acquire a superiority in the field, and to enter Vienna a second time as a conqueror. This success was chequered, indeed, by a sanguinary defeat at Aspern; but the victory of Wagram reinstated him in his superiority, and the advance of a Russian force left the Emperor Francis no other alternative than peace. A treaty was concluded on terms less humiliating than was anticipated, the cause of which was unknown at the time, but was soon found to be a consequence of Francis consenting to give his daughter in marriage to his conqueror.

By the peace of 1809, the Austrian empire was reduced to a population of 20,000,000. The diminution of her power was still greater from the cession of her frontier line; and France might, for a considerable time, have overawed and controlled her, had not the extravagant march to Moscow deprived Bonaparte, in a few weeks, of that mighty army which appeared to ensure the subjection of the Continent. The subsequent successes of the allies led, as is well known, to the restoration of Austria in more than her former splendour.

We shall now proceed to give some account of the present state of this empire under the following heads: Population—Climate and physical aspect—Education, Arts and Sciences—National Character—Religion—Government and Laws—Army—Finances—Agriculture—Mines and Manufactures.

Population. 1. The treaty, or act of Congress at Vienna, in 1815, and the subsequent treaty of Paris in the same year, have confirmed Austria in the possession of the following territories:

Bohemia, containing a population of	3,150,000
Moravia	1,320,000
Austrian Silesia	300,000
Lower Austria	1,050,000
Upper Austria	650,000
Salzburg and Berchtolsgaden	200,000
Styria	800,000
Carinthia	280,000
Carniola	420,000
Friuli and Trieste	106,000
Galicia	4,850,000
Bukowine	250,000
Hungary	7,400,000
Transylvania	1,600,000
Sclavonia	500,000
Croatia	350,000
Venetian States	1,650,000
Istria	100,000
Dalmatia	300,000
Tyrol	650,000
Lombardy, and other acquisitions in Italy	2,000,000
Total	27,926,000

Yet this empire, so populous and fertile, wants, in a high degree, that consonance of national manners, and that congeniality of national feeling, which are so essential to ease in governing, and have so long formed the strength of France and Britain. Hungary and Bohemia, which form so large a portion of the imperial dominions, have little connection or conformity with each other, and still less with the remote provinces of Galicia or Lombardy. Add to this, that the Austrian cabinet, while inferior to none in diplomatic finesse, has frequently acted with a blind adherence to old prejudices, which we should little expect in a European state in the eighteenth or nineteenth century. Frederick II. who had such bitter contests with the Austrians, both in the field and cabinet, declares that, in the former, they were unconscious of the value of good generals, while in negociation they were perfectly untractable, so long as the aspect of affairs justified, in any degree, their exorbitant demands. What better opinion were we at liberty to form in the present age, when we saw their army entrusted to a Mack, and preparations of defence delayed until the French were marching on Vienna? The grand source of future aggrandizement to Austria is to be sought, not in the acquisition of additional territory, but in the improvement and consolidation of her present dominions. This doctrine, applicable to all countries to an extent seldom apprehended by their rulers, is of the most urgent importance to a state, whose deficient instruction, languid intercourse, difference of language, and blind attachment to hereditary usages, all concur to keep so many fellow-subjects in a state of alienation from each other.

It has become customary, particularly of late, to consider Russia as superior in resources to Austria;

Austria.

an opinion sanctioned, among other authorities, by an expression of Lord Grey, in one of the debates which regarded the conduct of our ministry of 1806-7, in respect to foreign affairs. On considering, however, the rigour of the Russian climate, the barrenness of a great proportion of the soil, the inconvenience of vast distances, and the general barbarism of the people, we are disposed to withhold our assent from this opinion, and to look with more confidence to the probable augmentation of the population and power of Austria. The following table will convey an idea of the relative density of the population of her different provinces:

	Inhabitants per square League.
Bohemia	867
Austrian Silesia	847
Lower Austria	766
Moravia	748
Galicia	732
Croatia	657
Upper Austria	554
Styria	504
Hungary	495
Military frontiers of Sclavonia	470
Carinthia	453
Sclavonia	440
Transylvania, and its military frontiers	437
Military frontiers of Croatia	390
Bukowine	318
Military frontiers of Hungary	295

It is remarkable, that Lower Austria, though highly fertile, is not so well peopled as the manufacturing countries of Bohemia and Silesia. It is still more remarkable, that the mountainous tracts of the latter are found to contain a denser population than the rich plains of Hungary. The average of the whole empire is 579 inhabitants to the square league, a proportion hardly more than the half of that of France and England. Can there be a more striking proof of the improveable powers of the empire, when we consider that, of the countries just mentioned, the latter is, in point of soil and climate, inferior, and the former by no means superior to Austria?

No country, with the exception of Russia, comprises such a diversity of distinct tribes or races as the Austrian empire. The German part of the population does not extend in considerable numbers beyond the provinces of Upper and Lower Austria, a portion of Moravia, and particular parts of Styria and Carinthia. Bohemia, although surrounded by a German population, contains many districts inhabited only by its aboriginal tribes; while, in Hungary and Austrian Poland, individuals of German extraction are very thinly scattered. The most numerous of the varied races of this empire is the Sclavonian, a generic name now in a great measure lost in the subdivisions of Croats, Rascians, Carniolians, Bosniacs, &c. The Rascians, or Illyrians, are descendants of the ancient inhabitants of the vast tract known to the ancients by the name of Scythia. The fate of war has placed them alternately under the Turkish and Austrian dominion; their language is a dialect of Sclavonian mixed with the Illyrian. Some of their tribes lead a pastoral life, and follow the habits of plunder natural to wanderers; while others are stationary, and have made some progress in the ruder kinds of manufactures. Jews are scattered in various directions throughout the Austrian dominions, particularly in Bohemia, Moravia, and Galicia. Without being numerous, they find means, especially in Galicia, to transact most of the mercantile affairs of the country.

Hungary, the most extensive and most fertile of the great divisions of the Austrian Empire, is perhaps the most backward in point of civilization and knowledge. Many a rich tract, capable of supporting a crowded population, is here allowed to remain in pasture, in consequence, partly of the ignorance of the cultivators, and partly of that most absurd law which deprives the peasant of the right of holding landed property. The extent of the evil is most sensibly felt throughout Lower Hungary, the inhabitants of the northern part of the kingdom being accustomed to greater exertion, and being even known to possess occasionally little properties of their own. Another cause of the ignorance and backward state of Hungary, is the difference in point of language, manners, and religion, of various portions of its population. These have settled in it at different times, and from different causes, without becoming blended with each other in the manner that takes place in an industrious and populous community. The majority of the Hungarian tribes are of Sclavonian descent, but they are mixed with a variety of other nations, such as Armenians, Jews, Macedonians, and followers of the Greek church. The few Germans settled in Hungary are originally from the south of the empire, particularly Suabia and Bavaria.

Bohemia reckons above three millions of inhabitants, the chief part differing, both in language and in national feeling, from their German neighbours. They have even a decided aversion to the latter, and confine their national predilection to the Hungarians, who are said, in return, to esteem them more highly than their other fellow-subjects. The power of the Sovereign is much greater in Bohemia than in Hungary, for it comprises the legislative as well as the executive department. Notwithstanding this strange anomaly, Bohemia is the least backward of the Austrian provinces, whether we look to education or the labours of productive industry. The efficacy of regular habits, and of a compact population, in bringing aid to the executive power, is strikingly exemplified in the number of soldiers raised in Bohemia,—a number almost equal to that which is supplied by the far more extensive territory of Hungary.

Climate and Physical Aspect.

2. The difference of elevation of soil causes as great a difference of temperature in the Austrian empire as in any country in Europe. At Vienna, situate less than 400 feet above the level of the sea, the medium of annual heat is about 51° of Fahrenheit; at Gratz, a degree farther to the south, the medium is only 49°, the elevation being nearly 700 feet. Again, on the eastern frontier, Saltzburg, situate in the vicinity of an Alpine range, has an average temperature of only 47°, while at Prague, two degrees farther north, it is 48°.

Vienna, situate in a plain, intersected in a variety of directions by the Danube, the waters of which are here slow in their course, would be by no means healthy, were it not for the frequent breezes, which clear the air of unwholesome exhalations.

The Austrian dominions may be divided, in point of climate, into three regions, of which the southern comprises the provinces adjoining to Italy, with a part of Croatia, and extends from N. lat. 42° to 46°. We here find the olive, the myrtle, the vine, the fig-tree, and even the pomegranate. The depth of winter may be compared to the month of March in a northern climate. The middle range extends from the 46th to the 49th of north latitude, comprising Austria, properly so called, a great part of Hungary, and a portion of Moravia and Bohemia. The olive is no longer found to grow in this latitude, but vines and maize thrive in favourable situations. Winter lasts between three and four months; the spring is mild, though rainy; the summer warm but variable; the air is in general healthy, except in the neighbourhood of the marshes of Hungary, which are proverbially fatal to German settlers. The northern region comprises Galicia, a part of Hungary, a great proportion of Bohemia and Moravia, with the whole of Austrian Silesia. Winter is here severe, and lasts fully five months; vines and maize are no longer to be met with, and even wheat requires a choice of situation; but the summer heats, particularly in the valleys, are greater than we are accustomed to in Britain.

If we cast our eyes on a map of the imperial dominions, as, with the exception of the Polish part, they stood before the late annexations, we see them surrounded by a chain of mountains in almost every direction. Hungary is covered by the Carpathian range, which extends all the way to Silesia, and is even connected with the great circular barrier of Bohemia. To the eastward lies an elevated territory, in the direction of Bavaria, while, in the south, the line of discrimination from Italy and Illyrium is drawn with still more marked features. The highest mountains belong to the southern range; those of the north seldom exceeding two or three thousand feet, while those of the south frequently approach to four thousand. In the interior of the empire, and particularly in Hungary, there are levels of great extent, and the average height of many of the hills may be put down at only six or eight hundred feet. Strictly speaking, the whole of the mountains along the southern part of the Austrian dominions, and even those on the north, belong to one great range, extending, under a variety of modifications and names, all the way from the Alps to Russia. The latitude being temperate, or rather warm, these varieties of elevation present a striking difference in vegetable produce; the lower part being covered with vines, or rich crops of corn, while the adjacent elevation exhibits a picture of Norwegian sterility. Some provinces abound with picturesque views, and remind the traveller of the magnificent scenery of Switzerland. Styria, in particular, has its glaciers and perpetual snows, its rumbling cascades, its tremendous avalanches, and its green pasturages, in the region of mist.

Lakes are frequent in certain parts of the Austrian dominions. In Upper Styria, they owe, as in the Highlands of Scotland, their formation to the natural collection of water in valleys pent up in all directions; a description, however, which does not apply to the lakes in the level part of Hungary. Those are more properly marshes, and form, as in modern Greece, a striking indication of neglected agriculture. Large tracts are in this manner lost to every useful purpose along the banks of the Danube, the Drave, the Save, and other rivers of less magnitude.

Hungary may be called a vast plain of sandy soil, marked in certain districts by the highest fertility, in others by absolute barrenness. Galicia is less level than Hungary, but may likewise be called, in general language, a sandy plain of great extent. Moravia is marked by more prominent features; and while its soil presents, on the southern slope of its hills, the fertility of Lower Austria,—the northern side is found too cold for the cultivation of the grape. The inhabitants are active, and at a farther distance from primitive simplicity than the majority of their fellow-subjects. But the garden of Austria, and indeed of Germany, is the great valley, extending on either side of the Danube, to a considerable way above Vienna. Unfortunately, the riches of nature have not as yet been adequately improved in this region; the peasantry, though possessed of the greatest honesty and sincerity, being devoid of intelligence or activity. These good and bad qualities are not confined to the country; they form the groundwork of the character of the inhabitants of the capital, although necessarily modified by the habits produced by permanent assemblages in one spot.

The Austrian territory is traversed by a number of rivers, of which by far the most interesting is the Danube. It receives about 40 rivers from north and south, before entering the imperial dominions, and about 100 more flow into it before it falls into the Euxine, after a course of nearly 1500 miles Its bed becomes perceptibly widened by the influx of the Ens, at some distance above Vienna; and its subsequent breadth, though very various, may be said, in a general way, to be of one, two, or three miles. It is bordered throughout almost its whole course in the Austrian territory by ridges of mountains, the distance of which from the water is generally greater on the right than on the left bank. It is of sufficient depth to bear shipping throughout the whole Austrian dominions, and to admit, in Hungary, of vessels of considerable size. But, unfortunately, this noble stream is not fitted for easy navigation; its banks are often steep and rocky, its current rapid, and its bed encumbered with shoals. The height of the banks and the frequent windings prevent the use of sails to the extent practised on the Rhine and the Vistula. It is necessary, therefore, to tow almost all the way, and the boats, as well as the track along the banks, are as yet in a very rude state. A similar negligence prevails in regard to Canals, in which the Austrians have hitherto made very little progress.

The Austrian rivers, and in particular the Danube, teem with myriads of fish. The same is true of the various lakes scattered in different parts of the coun-

Austria.

try. Some kinds of salmon in the Danube are of so rich a flavour as to enter regularly into the list of presents made by the princes residing in the neighbourhood of its banks to their respective superiors. An attempt was lately made to convey some of this choice breed to the Rhine, by putting them into boats of such a construction as to admit the ingress of the water. The plan was to tow these boats up the Danube, as far as Ulm, and afterwards to reach the Neckar by means of some of the lesser rivers. It failed, however, and the undertakers had the mortification to see most of the fish perish by the way, in consequence, perhaps, of the smallness or improper construction of the boats.

Education, Arts and Sciences.

3. There exists, in point of education, a remarkable difference between the North and South of Germany. This difference is owing to the operation of political and moral causes—such as the difference of the form of government; the greater number of free towns in the north, and of public establishments; and, above all, to the predominance of Protestantism. It has long been a point of fashion and competition among the petty princes in the central and northern parts of Germany, to patronize literature. *Un homme de lettres* is there, as in France, a personage of considerable importance. Attempts have indeed been made, during the last and present age, by Joseph II. and the late Sovereign of Bavaria, to improve the universities, and to found academies, in their respective territories. The Academy of Munich, in consequence of the patronage of the latter, now occupies a prominent rank among literary bodies; and in Vienna, considerable progress has been made in the method of teaching Medicine, Surgery, and Botany. But in other respects, whether we look to schools or universities, the state of instruction in Austria is very imperfect. The innovations of Joseph were too abrupt to last; they have all disappeared except his primary schools. The hereditary states alone possess the means of tolerable education, the great provinces of Galicia and Hungary being in a manner deprived of them. Still there exists throughout this empire a patient and pains-taking industry, which will eventually prove highly favourable to the dissemination of useful knowledge. A stranger, on entering a German school, is struck with the arrangement, the gravity and the silence that prevail throughout. Several towns in Austria have Gymnasia or Academies somewhat similar to the Lycées in France,—calculated for teaching, not so much the classics as the introductory part of Mathematics, Medicine, or Law.

In the Academy of Medicine and Surgery at Vienna, the buildings are spacious, the professors numerous, and well qualified. The access to great Hospitals, to collections of Natural History, and to an extensive Botanical Garden, are all important facilities appended to this seminary. In fact, Vienna has held a distinguished rank in medicine since the days of Van Swieten, the opportunity of practical observation afforded by a large city, and the liberality of the public establishments, rendering this capital the resort of medical students from distant provinces; exactly as Göttingen is the point of attraction for moral and natural philosophy. Chemistry, however, has hitherto been little cultivated at Vienna; natural history more.

Austria.

Vienna has likewise an Oriental Society, a Veterinary School, and some institutions for teaching the Fine Arts. These, however, are all, except the medical, inferior to correspondent establishments in the north of Germany. Another subject of regret is, that a youth, after making a certain progress at school or college, finds little means of farther advancement from instructive society at Vienna. A thirst for information is little felt among a people occupied only with the tranquil enjoyment of the good things of this life; a people unambitious, uninquisitive, and disposed to go over the same tract as their fathers and forefathers. It is in scenes of agitation that the faculties are called forth; they become dormant in a state of general and continued acquiescence. The only feeling likely to stimulate minds of this heavy texture is the desire of acquiring property; and, in fact, trade of one kind or other forms the chief sphere of individual activity throughout the south of Germany. Such is the true cause of that literary apathy ascribed by some foreigners to the restraints imposed by government on the press;—restraints of no great severity, and certainly not intended to check the progress of useful inquiry.

Still Austria is not wholly devoid of names of eminence in literature. Frederick Schlegel is well known by his publications on the language and philosophy of India, and his brother William, by his translation of Shakespeare, and by his admirable works on dramatic criticism. To these are to be added the names of a few poets, and of a greater number of geographical and statistical writers. Hammer, the founder of the Oriental Society at Vienna, has published a translation of a Persian poem of some extent, and, like Wieland, has laboured to transpose into the German language the ornaments of the figurative style of the East. Etymology is a study suited to the laborious habits of the Germans, and on this, as on many other subjects, they have given us, if not finished works, the materials at least of valuable compositions. With the application of a better method, and with rigid compression, a variety of useful treatises might be extracted from the labours of the German literati.

Prague has a university of high antiquity, but of little reputation at the present day. The Catholic clergy are generally educated in humbler seminaries than universities. Without much pretension to literature, they bear the character of conscientious attention to their pastoral charge, in particular the country curates. Oratory forms no part of their studies; a German congregation meets, not for the purpose of being gratified by a pathetic address, but of fulfilling, soberly and tranquilly, a religious duty. Sermons in this country consist, accordingly, of little else than plain moral lessons, deduced from the Sacred Writings; and the reputation of a pastor rests chiefly on his attention to the sick, and the performance of private and unostentatious duties.

Several establishments have been formed of late years in Austria for the education of officers. The principal is the Military Academy of Wienerisch,

Austria. Neustadt, in the neighbourhood of Vienna, where the teachers are generally Engineer officers, disabled by wounds or otherwise from service. The pupils consist of young officers, or of youths of genteel families, preparing for the service. There are two other military seminaries in the capital, and some smaller establishments in the provincial towns.

As to travelling for the purpose of information, the Austrians have in general much less inclination than the English, or their German brethren in the north. Some examples, however, there are of men of science repairing to distant regions, such as M. Jacquin and Mohs who went to America in quest of plants unknown in Europe. Schultes, Gebhast, Mebzer, and Bremer, have also found means to render their travels instrumental to the diffusion of knowledge.

In mechanical inventions the Austrians have made that progress which may naturally be expected from a people, who, with a deal of patience and perseverance, are not in possession of the advantages of improved machinery. The result of their discoveries is, therefore, rather the gratification of a fancy, than that practical application to a productive purpose, which tends so greatly to cheapen labour in Britain. One German artist frames a machine to perform the functions of a chess player; another makes a head capable of an imitation of the human voice, while a third combines in a *panharmonicon* the most varied sounds of music. That instrument may, in fact, be called a concert in itself, a number of instruments being made to play simultaneously with the greatest precision.

The fine arts, with the exception of music, have hitherto made little progress in Austria. To find an eminent painter or sculptor there would be a matter of no small difficulty. But when we come to think of music, who can forget that Haydn and Mozart were formed at Vienna? If they are inferior in grace and melody to Italian composers, they are not to be surpassed in the grander powers of music. A foreigner cannot receive a higher gratification at Vienna, than by being present at the Oratorio in commemoration of Haydn. Architecture is still in its infancy in Austria. An Architectural Society has been lately instituted at Vienna, but most of the public buildings have been planned by foreign artists. Engraving, demanding rather patience than exertion, has been cultivated there with considerable success.

National Character. 4. The Austrian national character is marked by the same features as that of the German nation at large. Sincerity, fidelity, industry, and a love of order, are all conspicuous in them, and would long since have entitled them to fill a distinguished rank in the scale of European civilization, had not their beneficial operation been counteracted by a prejudiced government, a deficient system of education, and an illiterate priesthood. The consequence of these unfortunate drawbacks is the transmission of similar habits from father to son, a blind adherence to old usages, and an extravagant deference to hereditary rank, in the promotion of civil and military officers, which proved one of the great causes of the continued defeats in the late wars with the French.

In Austria, as in Britain, females enjoy a greater degree of freedom before marriage, than it is thought expedient to allow them in France. In domestic life, they act a modest and attentive part; fixing the predilection of their husbands, not, indeed, by the attractions of conversation, but by a mild and steady fulfilment of the duties of a wife and mother. They are thus probably more happy than the fair sex in France, although possessed of much less influence, and occupying a less conspicuous part in society. The lower orders are distinguished by similar virtues. In some districts we may visit village after village, without hearing of a single instance of domestic disquietude. The care of children, the habit of labour, and attendance on Divine worship, occupy all their thoughts. In Vienna, females form the chief attraction of society to a foreigner. Most of them speak French with fluency, and prefer it to the Austrian dialect of German, which is particularly unpleasant, having a slowness of accent and a hissing tone, extremely ungracious, particularly in the mouths of the common people.

The habitual assiduity of the Austrians leads them to cultivate, by preference, those occupations in which straight forward industry affords the means of success. Hence their progress in mechanics, and the flourishing state of many of their manufactures. Another feature in the German character, and one at first somewhat difficult of explanation, is their predilection for music; a passion found to exist in the humblest ranks, and under the least favourable circumstances. We meet here, in villages, with wandering musicians performing on trumpets made of the cherry-tree wood, or on the most grotesque violins. If in vocal music they yield to the Italians, they fully maintain the competition in point of instrumental performances—a taste which prevails as well in the fertile parts of the empire, as in the secluded spots of Tyrol and Carniola; forming a curious example of the results attendant on the continued prosecution of an elegant study by a slow and apparently inanimate people.

No country presents fewer examples of criminal offences than Austria. Year passes after year, without any necessity for the infliction of a capital punishment. Averse as the inhabitants are to Frenchmen, particularly in the shape of military invaders, we know of no example, during any of the late invasions, of those secret assassinations which occurred so frequently in Spain.

Of the manners of the inhabitants of the mountainous provinces of the empire, we may form an idea by fixing our attention on the Styrians and Carinthians. The middle range of these mountains presents a scanty pasturage; their upper parts are covered with tracts of snow, while the yew and fir are the only trees which are seen to raise their heads amidst the tempest. The inhabitants of these elevated districts are simple, hospitable, and religious; content with the produce of their land and cattle; cheerful and frank as simplicity and moderate desires can make them, they have no wishes beyond the limits of their own territory. The only feeling which prevails among them with any keenness, is religious zeal. They are ardent Catholics, and open to all the idle suggestions of an illiterate priesthood.

Austria.

They are in the habit of undertaking distant pilgrimages, which they are taught to consider as the best means of obtaining the forgiveness of trespasses. Along their roads are scattered mystic chapels, crosses, and other indications of the exercises of devotion. The traveller is often fortunate enough to find beside these religious erections a spring whose waters afford him a delightful refreshment, when pursuing his way along a confined valley. He finds himself here among a primitive race, who are unacquainted with the arts of men in a more civilized state, and are easily guided by an appeal to the heart. Their language is sonorous, and the echo which repeats the call from the mountain side, often proves a useful warning to the stranger when wandering from the path, or when approaching to the brink of a precipice. Often, in the course of his journey, does he meet with inscriptions, in which the hand of a friend or a brother has recorded the name of one who has fallen a victim to the storm or the torrent.

Religion.

5. Austria has long contained a considerable diversity of religious sects, without having suffered from their contests in any part of her dominions except Bohemia, the country of the well known John Huss, and Jerome of Prague. In the other provinces such excesses have been avoided, partly from the moderate character of the inhabitants, and partly from the tolerant spirit of the Imperial Family. There can be no doubt, however, that, had the Reformation happily made progress in the Austrian dominions, the result, as in the north of Germany, would have been a very material advancement in all departments of productive industry. Trade, manufactures, literature, are all cultivated with superiority in the north; and if the agricultural produce of the south be larger, the cause is to be sought merely in superiority of soil and climate. Toleration, however, existed virtually for a considerable time back in Austria, and it received a formal sanction from a law of Joseph II., which extended indulgence even to Jews and Mahometans. The Archbishop of Vienna is the head of the Catholic clergy in a civil capacity; but the Bishop of St Palten appoints the regimental chaplains, and is accounted the superior of all clergymen doing duty with the army. Church patronage rests with the Sovereign, to the exclusion of the influence of the Pope. Convents, formerly numerous in Austria, have been considerably reduced during the last thirty years; but the church property is still very considerable.

In computing the relative number of different sects, it is common to estimate the Catholics at two-thirds of the whole. Protestants are not numerous; the Austrian people at large being too little enlightened to exchange a worship which dazzles the imagination by its pomp and ceremonies, for one whose chief appeal is to the understanding. The Greek church has no inconsiderable number of votaries scattered throughout Galicia, Hungary, Croatia, and Transylvania. These are superintended by a number of Bishops, some of whom recognise for their head the Archbishop of Leopold, while others, who differ in point of creed, are under the jurisdiction of the Archbishop of Gran in Hungary. The latter are particularly numerous in Transylvania. The followers of the Greek church, in one part or other of the Austrian dominions, are said to exceed the number of 2,000,000;—a number in a state of gradual increase from the occasional influx of their brethren from Turkey. These new settlers are generally engaged in trade, and pass for possessing no slight share of the address and artifice attributed to the Greek merchants of the present day. Galicia comprises a body of Armenian Catholics; a sect not wholly unknown in Hungary. The Protestants, including both Calvinists and Lutherans, amount, probably, to nearly 3,000,000 throughout the whole empire, of which Bohemia and Moravia contain a very insignificant proportion. The well known association of Herrnhutters or Moravians, owes its origin to an Austrian province, and takes date from the middle of the fifteenth century. The number of Jews under the Austrian dominion may amount to 300,000. Joseph II. took the lead of Bonaparte in an attempt to incorporate them with the mass of his subjects, by extending to them the enjoyment of similar privileges. He found, however, that their habits, if they yield at all, give way but very slowly, and that ages will be required to identify them with their Christian fellow-subjects. In tolerating Mahometanism, Joseph had in view the promotion of commercial intercourse with Turkey, a number of traders of that country being in the habit of travelling, and even of settling in Austria.

Government and Laws.

6. There exists a great diversity in the constitution of the component parts of this extensive empire. It may be safely assumed, that the disadvantage from want of unity, already noticed, will infallibly continue to a considerable extent, until there be established a greater similarity in point of legislation. At present, each of the great divisions constitutes an unconnected body, and the whole resembles rather a federative association than one compact consolidated state. In the Austrian provinces, the constitution is understood to be founded on a great charter, passed so long ago as 1156. In Bohemia, the principal laws are of more recent date, and hardly go back two centuries. In Austrian Silesia, there exists a great complexity of public regulations, while Galicia, differing still more essentially from the other provinces, traces back the basis of its constitutional dependence on Austria no farther than 1773.

Hungary is wholly distinct from the other divisions of the monarchy, and claims to be governed by laws altogether different. The first of these is traced back so far as the end of the ninth century; others date from the thirteenth, and confirmations of the privileges of the nobility, with limitations of the imperial power, were successively passed during the seventeenth and eighteenth centuries. Here the emperor exercises the supreme power, only through the medium of the States or Parliament. He may dispose of the great offices of the kingdom, but under the restriction of giving them not only to natives of Hungary, but to men of a certain rank. In this land of aristocracy, no plebeian, of whatever talents, is entitled to rise in a public office above the humble station of a clerk. The Emperor is accounted the constitutional President of the Diet, but he

Austria. may delegate a representation to one of his great officers. A general levy, or "insurrection," as it is termed, must, like other measures, proceed from the legislative assembly.

The States, or parliamentary meetings, differ in different provinces of the empire, but are generally divided into four classes; the prelates, the higher nobility, the knights, or gentry, and the deputies of the boroughs. It is a general meeting of these classes that constitutes the Hungarian Diet. The prelates have the right of voting first. The nobility possess not only an exclusive title to public appointments, but the daughters of the less affluent families among them are admitted to an establishment in convents, on proving their rank, or, as it is called, the number of their quarters, in the manner pointed out by law. The Diet of Hungary is generally convened once in three years, and meets at Presburg or Buda. The Prince Palatine, or, in his absence, the noble of highest rank, presides at the *Tabula procerum*, having on his right the primate, along with the archbishops, bishops, and other dignitaries of the church. The second board, or *Tabula inclytorum*, has for its president the imperial representative, while the third division of the Diet comprises the deputies of towns, the secretaries, and other inferior officers. The deliberations proceed either on the propositions of the sovereign, or on the bill of grievances of the subjects. The Diet is generally divided into chambers, who discuss business separately, and communicate with each other by the medium of members. In case of non-agreement, the whole are made to constitute one assembly, in which a decision is made by plurality of votes. An act of the Diet receives the force of law when sanctioned by the Emperor, or King, as he is invariably termed in Hungary, and it seldom happens that any serious division takes place between the Diet and the executive power.

Such was formerly the extravagance of aristocratic notions in Hungary, that no plebeian, or person engaged in trade, could carry on, in his own name, a law-suit against one of the gentry. It was necessary that the town where the plaintiff resided, should come forward and assume the cause of its citizen. This absurd usage was abolished in 1802. Still, however, a peasant or farmer can seldom bring, in his own name, an action against one of the gentry; he must generally do it through the medium of his superior or landlord. The right of possessing land in Hungary being confined to the privileged classes, it follows that a donation of land by the Sovereign is tantamount to conferring a title of nobility. The land cultivated by the vassal is, of course, altogether the property of his superior; but arrangements are made for allowing the former to reap, as far as that is practicable, in so ignorant a country, the fruit of his labour. The corvees and taxes on the *tiers etat*, so much complained of in France before the Revolution, prevail here in all their extent. Hence the importance to the boroughs of acquiring the privileges of free towns, and enabling their inhabitants to possess land without a title to nobility.

The Hungarian landholder is exempt from all imposts. Tithes, toll-dues, a tax called the thirtieth penny, the contributions for soldiers, all pass over his head, unless he become pledged to them, along with his brethren, by a specific act of the Diet. In return for all these exemptions, they are bound to rise *en masse*, and to serve personally under their Sovereign, whenever a war receives the approbation of a General Diet. It will not escape the observation of our readers, that these fiscal privileges, always the subject of boast among the Hungarian noblesse, and, in former years, not unfrequently a ground of quarrel with their Austrian Sovereign, do not amount, in fact, to anything like an entire exemption. Public burdens, however disguised, fall eventually, with a considerable share of equality, on all classes. In Hungary, the inhabitants of the towns are obliged to seek, in the enhanced price of the commodities, sold to the landholders, an indemnity for their greater share of taxation. The late Emperor Joseph II. was disposed to abrogate many of these pernicious usages, but his character was not well fitted, nor did he reign long enough to accomplish the task.

In the hereditary provinces, or Austria Proper, the power of the Emperor is much greater. In the eye of the law, he is the supreme judge, the fountain of dignity, the centre of legislative as well as of executive power. He has a right to impose taxes, to regulate the affairs of the church, and even to modify religious worship, in whatever is not accounted a fundamental article of faith. He may tolerate any religion, oppose the papal bulls, and prohibit the publication of the pastoral letters of bishops. This power, delicate as it is in a Catholic country, has been sometimes exercised by the emperors, when they had occasion to urge political points of importance with the sovereign pontiff. At such times they have not scrupled to forbid their subjects to remit money to Rome, and have been known to interdict all correspondence between the Austrian and foreign convents. A more important prerogative is that which they possess to impose taxes on church property throughout Austria and Galicia.

The executive government of the Austrian empire at large consists of four great departments, and owed its present organization to the counsels of Maria Theresa. One of these establishments regulates all home affairs; foreign affairs are managed by another. Military matters are subjected to the third great department, while the fourth and last regulates the interior administration of Hungary. The name of Aulic is not confined, as is vulgarly imagined, to the Military Board; it is common to several councils, and is given, among others, to the Board of Finance. Another department, sufficiently indicative of the backward state of the science of government in Austria, is that which superintends the working of mines for public account.

In this country, as in France, the attention of government has been lately given to a more easy exposition of the fundamental rules of jurisprudence. A first attempt was made so long as forty years ago, and a code was published in 1767 in eight folio volumes. This performance had two great defects, its size and its want of classification by general rules. While of little use to lawyers, it was wholly unprofitable to the public at large. Instructions were accordingly

Austria.

given to an eminent civilian, Von Horten, to recast it in a condensed and improved form. Considerable progress was made in this before the death of Joseph II.; and in 1794, under the auspices of the present sovereign, the first part of the civil code came forth in a new form. A few years after, the whole appeared in an amended shape, and government appointed several local commissions, with instructions to make reports on its applicability to the different provinces. Printed copies of the code were distributed in all directions, and the universities enjoined to take it into mature consideration. The definitive correction and promulgation of the code were retarded by various causes, and particularly by the unfortunate wars with France, so that its actual adoption did not take place until the beginning of 1812. The criminal code had not been so long withheld; it was promulgated in 1803, and introduced into practice in 1804.

Military Establishment.

7. In a country where the executive power is not subjected to animadversion, or to the exhibition of official statements, it is a matter of no small difficulty to compute the extent of the military force. It was supposed that, in the campaign of 1805, the Austrians had on foot above 250,000 *effective* troops, of whom nearly a fifth were cavalry. In that of 1809, this force of regulars was backed by a considerable body of reserve, and by above 100 battalions of militia, known by the name of *landwehr*; but the state of discipline of the latter was not such as to offer any effectual resistance to the progress of the French. The war establishment, in *regular* troops, can scarcely be estimated, we apprehend, above 250,000 men; and half this number may perhaps be taken as near the amount of her effective peace establishment.

The *irregulars* in the Austrian service are drawn, in a great measure, from Croatia and other provinces along the Turkish frontier. About sixty years ago, the greater proportion of the Hungarian troops fell under this description; but the wars with Prussia having taught, by dear bought experience, the value of discipline, the Austrian commanders, in particular, Marshal Lascy, gradually accomplished a change, and converted hordes of flying squadrons into compact and regular regiments.

In the Hereditary States, and we believe in all the empire except Hungary, the levies are made, in the first instance, for militia duty, from which it is no difficult matter, in an absolute government, to accomplish a transition to the line. In Hungary, recruits are levied in virtue of an act of the Sovereign and the States, after the promulgation of which, the different Magnates find means to enlist the requisite number on their estates. The chief disadvantage of the necessity of a legislative sanction in Hungary, is the publicity thus given to the extent of military preparation. The length of service in the Austrian army has undergone alterations during the present age, and it now admits, as in Britain, of limitation by periods. In time of peace, the officers have no difficulty in obtaining a furlough for the greatest part of the year. Veterans and wounded men are entitled to admission at the military hospital of Vienna, or to a small out-pension.

Though, to an English traveller, manufactures would appear to have made little progress in the Austrian dominions, they stand on a footing equal to that of their continental neighbours, and supply government with most of the materials of war. Clothing, arms, ammunition, harness, are all furnished at different stations in Bohemia, Moravia, and the Hereditary States. The horses for the light cavalry are drawn from Hungary and Galicia; those for the heavy cavalry, chiefly from Bohemia and Moravia. The disposition of the inhabitants of most of the imperial territories, is well adapted to a military life. They are generally accustomed to pass their time out of doors, to indulge in active exercise, to follow the chace, and to occupy themselves with the care of horses. To such men marching and encamping is but a slight variation from established habits. The fire of the nightly watch is not more uncomfortable than that of their smoky cottages; while a loaf of bread, a slice of coarse pork, and a glass of spirits, supply them with all the nourishment they desire. In point of resources, therefore, Austria is one of the greatest of military powers,—her deficiency has hitherto been in their application. Too much attention is given to the *minutiæ* of individual exercise, without considering how seldom these niceties can be made applicable to collective numbers. Hence an endless list of military instructions, and a complexity of evolution, such as to be hardly practicable in a review, still less in a day of battle. At the same time, there exist very material omissions in regard to the method of moving large bodies of men. Will it be believed, that the Austrian regulations contain no explicit directions for a change from line into column, whether for attack or defence! Hence, in a great measure, the loss sustained at Essling and Wagram by long exposure to the French artillery. Official instructions are given for the manœuvres of battalions and regiments, but nothing is said of those of brigades, or larger divisions. The consequence is, that the Austrians form their line very slowly, and find, when it is once formed, a deal of difficulty in executing any other movements than those to front and rear. They have very little dexterity in separating, reuniting, or supporting each other at short notice.

The military schools at Vienna having been found highly useful, the government has adopted the plan of establishing them elsewhere. The consequence, it is to be hoped, will be a gradual correction of the defects hitherto attendant on deficient education and blind patronage. Few services are more discouraging than the Austrian to an officer who has not the advantage of rank.

Finances.

8. In Austria, a country possessed of very little foreign trade, the taxes are chiefly levied on the land, and on objects of interior consumption. Joseph II., desirous of new modelling this as well as other departments, proposed the adoption of a land and poll-tax on a uniform plan. As a necessary preliminary, *arrangements* were made for a general survey of the landed property of the empire, and several years devoted to that important operation. It was, however, too unskilfully conducted to afford anything like a satisfactory ground to estimate the value of the different properties. No adequate allowance was made for the difference of plain and mountain, of fertile or barren

5

tracts. The consequence is, that the collection of this department of the revenue is still in a very imperfect state, although the tax on land and houses (*impot foncier*) forms necessarily the chief part of the Austrian revenue. In Bohemia, Galicia, and the Hereditary States, this important tax falls equally on all classes; in Hungary and Transylvania, it is borne, as we have already observed, by the farmers and inhabitants of towns, to the apparent total exemption of the *noblesse*.

The imperial demesnes form also a considerable branch of the Austrian revenue, particularly in Galicia. This source of income, which would be very great in a country like Holland or Britain, where landholders and farmers of capital would take the land at a rent, and relieve government of all farther superintendence, is comparatively inconsiderable in a country where the administration either has not the means or the judgment to throw off its hands, a task which must always be unprofitably managed by servants little interested in the produce of their labour. These crown demesnes are to be carefully distinguished from the personal property of the reigning family, the annual rental of which may amount to L. 100,000 Sterling a-year.

Another branch of revenue is derived in Austria, as in France, from the exclusive manufacture and sale of tobacco. This monopoly extends over the German dominions, but Hungary and Transylvania are not subject to it. Austria has likewise a duty on stamps, hair powder, starch, and various objects of luxury, among others, on the *rouge* used by the fair sex. Wine, beer, brandy, carriages, pleasure horses, are all subjected to taxation. A considerable income is levied from legacy duties, fees on titles of nobility, china, glass, and even from a toleration tax on the Jews. The financial embarrassments of the country, necessitated, in 1802, an increase of a full third on these duties, along with the imposition of two taxes of a different kind—a poll and an income tax. This rapid augmentation of public burdens made it be calculated, that throughout the empire no less than a fourth of the income of individuals found its way into the public treasury. To compute the total of the revenue is a point of no small difficulty in a country where taxes are complicated, and official accounts either withheld or irregularly published; but we are disposed to think, that L. 18,000,000 Sterling may form a probable approximation to the *gross* revenue of this empire.

The Austrian, like other governments, has had recourse, in its distress, to the circulation of paper money,—a measure attended with all the bad consequences incidental to immoderate issues on the part of an authority not responsible to its subjects. The public debt exceeds 150 millions Sterling; two-thirds of which, however, being created by the issue of paper, are by no means deemed repayable at their nominal amount. In fact, the repayment of a fifth part of that amount, will be accounted a fair retribution of the debt contracted in this paper at an advanced stage of its depreciation. The rule at the treasury was to raise prices as paper fell, and the eventual adjustment of accounts between government and the stockholder will probably take place in a manner similar to that adopted in France after the death of Louis XIV., under the direction of the brothers Paris, when a regular scale of estimates was formed on a retrospect to the value of government paper at the different periods of its issue.

Agriculture.

9. Agriculture is still in a very backward state throughout the Austrian dominions. The large proportion of church and other public lands, with the general want of education, have hitherto prevented the people from extracting an adequate return from their fertile territory. In casting the eye over these rich provinces, an observer is at a loss on which to fix as most favourable to the exertions of the husbandman. The uneven surface of the Hereditary States rivals, in point of fertility, the extensive plains of Hungary and Transylvania. Again, the portion of Poland, acquired by Austria, was perhaps the richest division of that ill-fated country. The following rough estimate has been made of the appropriation of respective proportions of the empire. Taking 70 as the integral, representing the whole surface, we shall have for

Mountains, heaths, marshes, lakes, roads, - -	26
Land under tillage, - - - -	12
Meadows and pasturage in an inclosed or improved state, - - - - -	7
Pasturage in a rude state, - - -	4
Woods and forests, comprising all uncleared tracts, - - - - - -	18
Vineyards and orchards, - - -	3
	70

The produce of the land along the Danube, from Vienna to the Bavarian frontier, has been greatly increased within the last half century, by the use of marl. The traveller, in pursuing this tract, sees in all directions a quantity of marl pits, wrought with great activity. Bohemia is naturally fertile, but its agriculture is in a very backward state, from the continued prevalence of feudal usages. Moravia has made greater progress, and furnishes an annual supply of corn for export. Hungary is in many parts so fertile as to produce an abundant crop, with very little exertion from the labourer. Here may still be seen the primitive practice of treading out the corn by horses and oxen. Galicia, under a better system, might be rendered productive in the highest degree. The same holds in regard to the adjacent Polish province of Bukowine. Maize is cultivated in Hungary and Transylvania; millet in Hungary, Sclavonia, and Carinthia; and even rice is found to answer in the marshy districts of Temeswar.

The product of the Vine, though far short of what it might be rendered, is a source of considerable wealth to Austria. The well known tokay is raised on the last chain of the Carpathian range, in the neighbourhood of the country of Zemplin. The district where it is cultivated is of the extent of 60 or 70 square miles; its qualities are various, the richest kind proceeding from the grape, with little or no pressure, while the inferior sorts are said to be made of the dried grape, reduced into a sort of pap, and mixed up with other Hungarian wines. We must not take for granted, that all the wine sold under the

Austria.

name of tokay is the product of the district just mentioned. The dealers find this fashionable name a very convenient passport for the produce of the adjacent districts, so that even in Vienna there is not a tenth of real tokay among the wines sold under that designation.

Tobacco is cultivated to a great extent in Hungary and other parts of the empire. Hops are raised in Moravia and Hungary, but more particularly in Bohemia, where in some districts they are said to approach in quality to those of England.

The stock of horned cattle is said to have decreased of late years in the Austrian empire, in consequence of the introduction of large numbers of sheep. It has been computed, on a rough calculation, that the Austrian dominions comprise about two and a half millions head of cattle, above five millions of sheep, and about one million of horses. The Hungarian horses are small, but active, and capable of great fatigue. Many of them are accustomed, in their early years, to wander in a wild state along their vast pastures, and are caught only when of an age to become fit for service in the field. Galicia and Moravia contain a large proportion of the above mentioned number of horses. The remainder are chiefly in Lower Austria; for neither Bohemia, nor the mountainous tracts on the south of the Hereditary States, contain any considerable number. There are four public establishments for the purpose of training horses in Austria, the principal of which is at Mezaehegyes in Hungary. In this, unquestionably the greatest institution of the kind in Europe, there are no less than 800 mares, of German, Bessarabian, Moldavian, Spanish, or Hungarian extraction.

Mines and Manufactures.

10. Hungary and Transylvania possess mines both of gold and silver. They have also what is much more favourable to the increase of their productive industry, excellent mines of copper. The tin of Bohemia is compared to that of Cornwall, as the iron of Styria is to that of Sweden. These metallic treasures are not confined to a single province, but sufficiently scattered to diffuse the means of employment throughout various parts of the empire. Another mineral product of the highest importance is coal, which is found in various spots of Bohemia, Moravia, and Hungary. Thirty mines are already ascertained to exist in the latter country, although so backward is the application of capital to useful purposes, that only two of them are as yet wrought. In Bohemia, Styria, and Lower Austria, this important branch of industry has been somewhat more cultivated, in consequence of the vicinity of the coal to iron ore.

Mines of rock salt are found in various parts of the Empire. Those of Bochnia and Wieliecka in Galicia are known to be the greatest in Europe. A number of others are found along each side of the great Carpathian chain; nay, they extend, with greater or less intervals, all the way from Moldavia to Suabia, along a tract which, including a variety of windings, is not short of 2000 miles. This tract comprehends the salt mines of Wallachia, Transylvania, Galicia, Upper Hungary, Moldavia, Upper Austria, Styria, Salzburg, and finally of Tyrol. They are found either at the base or on the ascent of great mountains; the salt extending in horizontal or undulating strata, and alternating with strata of clay, in which the saline substance is frequently observed to have made its way.

Austria.

Manufactures have of late years been considerably on the increase throughout Austria. Few countries are more abundant in the supply of raw materials, and this substantial advantage received a powerful, though ill-judged, co-operation on the part of Joseph II., who thought it expedient to resort to a prohibition of several kinds of foreign manufactures. Linen and hemp may be called the staples of the Hereditary States and of Bohemia. Different qualities are fabricated in different places, Moravia having generally the coarse stuffs, while certain parts of Bohemia carry the fabric to a point of great nicety. The ruder provinces of Galicia, Hungary, and Transylvania, have made little progress in these branches of industry, or in the manufacture of cotton cloths, which is considerably diffused through Bohemia and the Austrian states. Spinning machines have been introduced from England, but the price of the raw material is necessarily enhanced by the distance of land carriage. Woollen cloths are made throughout the empire, particularly in Moravia, but the quality in the remote provinces is very inferior.

No country is better adapted to excel in hardware manufactures than Austria. The mines in Bohemia, Styria, Carinthia, and Upper Austria, supply an abundant store of excellent materials. The steel of Carinthia and Styria is known and highly prized in England. Vienna, Prague, and Karlsbad, contain manufactures of this metal, and arms are made in great abundance in more than a dozen of different towns. Glass has long been made in great quantities in Bohemia and the neighbouring provinces; but the long continuance of the late wars was unfavourable to the ornamental species of this manufacture.

Concluding Observations.

The course of recent events has thus unexpectedly restored, and, in fact, more than restored, Austria to her high station among European potentates. The long continued exertions of Britain, the unsparing sacrifices of Russia, and, more than all, the extravagant attempts of Bonaparte, have redeemed the past errors of the cabinet of Vienna, and enabled her to reap the richest harvest of any of the allies from the spoils of the French empire. Her influence over the south of Germany is strengthened, and her ascendancy over Italy, formerly one of her weakest sides, is materially increased. The Low Countries, however rich and fertile, were at too great a distance from her other dominions, and too little connected with her by manners or national feeling, to form a first rate object of her policy. It is not too much to say, that the loss of them is fully compensated by the consolidation given to her Italian acquisitions by the incorporation of the Venetian States.

In the present state of France, there seems no likelihood of a renewal of a military contest with Austria, for many years. Italy is now doubly fortified against invasion; and the present generation of Frenchmen will listen to no enterprises of ambition beyond the Rhine. Austria may thus enjoy profound peace, if she be not deluded into projects of aggrandizement on the side of Turkey, or alarmed into a struggle with Russia on account of her possessions in Poland.

The writers upon Austrian Statistics are very numerous; but we shall content ourselves with referring in this place to the lately published and instructive Work of M. Marcel de Serres, entitled *Voyage en Autriche, ou Essai statistique et geographique sur cet Empire.* Paris, 1814. 4 vols. 8vo. (D. D.)

Situation.

AYRSHIRE, a county in the west of Scotland, considerable for its population and industry, is bounded by Wigtonshire and the stewartry of Kirkcudbright on the south, by the counties of Dumfries and Lanark on the north-east and east, by Renfrewshire on the north, and by the Irish Sea and the Frith of Clyde for about 70 miles on the west. It contains about 1039 square miles, or 664,960 English acres, of which nearly the half is under cultivation; besides several small lakes, Loch Doon being the largest, extending to about six square miles more. The three bailiaries of Kyle, Cunningham, and Carrick, into which this county is divided, have been described in the article in the body of the work, to which the reader is referred. The rock of Ailsa, and the Meikle and Little Cumbrae, situate from 1½ to 3 miles from the coast of Ayrshire, and nearly the same distance from the Isle of Bute, are attached to this county. (See HEBRIDES.) The valued rent is L. 191,605, 7d. Scots, and the real rent in 1811, of the lands, was L. 336,471, 10s. and of the houses, L. 22,823 Sterling. The division of property is considered not unfavourable to the prosperity of the different classes of the population, though it appears that more than a third part of the whole county is held under settlements of entail. The advantages possessed by Ayrshire, besides its sea-coast and several excellent harbours, may be traced to the coal and limestone found in great abundance in almost every part of it,—the one so necessary to its manufactures, and the other to its agriculture; and the chief natural disadvantage under which it labours is the humidity of its climate, aggravated by the quality of the greater part of the soil, which is a tenacious clay.

Extent.

Valued and real Rent.

Soil and Climate.

Agriculture.

Agriculture, according to the more approved courses of management, has nevertheless made considerable progress of late in this county. The old rotation of three consecutive crops of corn, followed by six years hay and pasture, has been very generally abandoned in the new leases; and, on the better soils, an alternation of white and green crops, and an interchange of tillage and pasturage, as in the eastern counties of Scotland, begin to prevail. The dairy is, however, the chief object of attention to the Ayrshire husbandmen, and their valuable breed of cows, and rich, yet mild cheese, known by the name of Dunlop cheese, are in great repute in most parts of Britain. Their horses, under the general name of Clydesdale or Lanarkshire horses, are equal, if not superior, to those of any other race in the Island; almost every small farmer, and the farms are too generally small, either rearing one or more himself, or purchasing them when young, and reselling them to the eastern counties after a year or two of very moderate labour. After all, it must be admitted that the agriculture of Ayrshire is much behind that of the counties on the east coast. No regular system of cleansing and manuring the soil, nor of fallowing and draining the wet lands, is to be seen throughout the greater part of the district. The size of the farms is commonly from 50 to 150 acres, affording little room for the employment of capital, or the division of labour; and yet the rents are surprisingly high—of some favoured spots not less than eight pounds or guineas the acre.

Manufactures.

Ayrshire, as a manufacturing district, seems to stand next in importance, among the Scottish counties, to the contiguous shires of Lanark and Renfrew. Various branches of the woollen manufacture are carried on to a considerable extent in different parts of it, in Kilmarnock alone, to the value of L. 30,000 yearly. Carpets, and the coarser fabrics, give employment to a considerable proportion of the inhabitants of that thriving town; and besides several public establishments there, and in other parts of the county, many private families in almost every parish take a share in the manufacture of blankets and coarse cloths; a part of which, after supplying their own wants, is carried to the fairs and markets of the county. Beith has long been noted for its thread manufacture. The cotton-works at Catrine are by far the most extensive of all its manufactories; employing, in 1811, 900 hands, who are said to have spun into yarn 10,000 lbs. of cotton wool, and made 35,000 yards of cloth every week. At Muirkirk and Glenbuck, pig and bar iron are wrought to a great extent, and founderies have been erected there and in other places. Leather, saddlery, earthen-ware, kelp, salt, are the only other kinds of manufacture worthy of notice in this county.

Commerce.

Ayr, Irvine, and Saltcoats, were, till very lately, the only harbours much frequented, and at these places there has long been a little trade with Ireland, America, and the Baltic, and a considerable trade coastwise. In 1807, the port of Ayr had 54 vessels, of which the burden was from 4000 to 5000 tons, and 82 vessels belonged to Irvine and Saltcoats, which carried 6795 tons. Coal is the staple article of export, and corn the most considerable of its imports; the ports on the Clyde having hitherto been the grand emporium of the west of Scotland.

This county exhibits instances of public spirit in its great land proprietors beyond any other in Scotland, or probably in the British empire. The harbour, and other works carrying on at Ardrossan, under the auspices of the Earl of Eglinton, and the harbour of Troon, and the railway from thence to Kilmarnock, formed almost entirely at the expence of the Duke of Portland, are worthy monuments, no less of the enlightened judgment and energy, than of the wealth of these two patriotic noblemen; and the distant prospect of remuneration, which it is much to be wished should be realized, can detract but little from the merit of such grand and princely undertakings.

Ardrossan Harbour.

The harbour of Ardrossan will, when completed, be one of the safest, most capacious, and most accessible on the west coast of Britain; possessing many advantages over the harbours in the Frith

Ayrshire.

of Clyde, situate in a narrow channel, which can be navigated only when the wind blows from particular points, and which, for upwards of 20 miles below Glasgow, is both shallow and dangerous. A circular pier of 900 yards was finished in 1811, and everything was then ready to begin the wet-dock, which, according to Mr Telford's plan, was to contain from 70 to 100 vessels in water 16 feet deep. The works have rather languished of late, and are not likely to be completed soon without public aid. It was part of the Earl of Eglinton's plan to raise a neat regular built town at Ardrossan, in which some progress has been made; and he has constructed excellent baths, which draw to it a number of visitors at the proper season.

The harbour at Ardrossan was only a part of the general plan, and that from which, viewed by itself, the smallest advantages perhaps were to be expected. The leading idea was to open up a direct communication between Glasgow, Paisley, and other large towns in the vicinity, and the west coast, instead of the present circuitous passage by the Frith of Clyde.

Canal.

A canal was therefore to be cut from Glasgow to Ardrossan, about $31\frac{1}{2}$ miles, at the estimated expence of L.125,000. Of this only a third has been yet executed, that is, from Glasgow to Johnstone, and this part has cost about L. 90,000.

Troon Harbour.

The harbour at Troon, connected as it now is with Kilmarnock, by means of an excellent railway, seems to possess almost all the advantages of that of Ardrossan, and promises to become, in a much shorter period, of vast utility both to the populous country around it, and to the noble undertaker. The pier is now carried into the sea more than 200 yards, and it is proposed to extend it 100 yards farther. At the present extremity, there is a depth of 17 feet at low water. One graving dock was finished about three years ago, which is much resorted to for the repair of coasting vessels; and another, 37 feet wide at the gate, is nearly completed, which will admit vessels of almost any burthen. Extensive warehouses have been erected; and a yard has been opened for building vessels, which is likely to be well employed.

Railway.

The railway from Troon to Kilmarnock, a distance of 10 miles, is now completed, and answers all the purposes for which it was originally intended. There are upwards of 3000 acres of coal fields in its course, which must in time indemnify the Duke of Portland for his outlay both on this and the harbour. Coals have been hitherto the principal article of conveyance towards the Troon, at the rate of 100 tons daily; and from thence timber, iron, grain, &c. are transported to Kilmarnock and the country adjacent. One horse draws with ease five tons downwards to the Troon, and three tons upwards to Kilmarnock. But locomotive engines, upon the principle of Mr Stephenson of Newcastle, promise soon to render horses unnecessary. The machine weighs $3\frac{1}{2}$ tons, and can carry along with it 25 tons, at the rate of four miles an hour upon an average. This railway has cost the Duke upwards of L. 50,000, and the harbour is estimated at about the same sum.

Population.

The comparative population of Ayrshire, as taken under the acts 1800 and 1811, will be seen from the following abstract:

1800.

Azores.

AZORES, or Western Islands. These form a range situate in the Atlantic Ocean, extending in an oblique line from north-west to south-east, between the 37th and 40th degrees of north latitude, and the 25th and 32d degrees of west longitude. It has been a subject of some controversy among geographers, to what quarter of the world they ought to be referred. Originally attached to Africa, they were afterwards, with evident impropriety, transferred to America, and are now more generally viewed as part of Europe; though their connection and general resemblance to the other African groups, rather incline us to adhere to the first arrangement.

It does not appear that the ancients had any knowledge of the Azores, or of any group in this sea, except the Canaries, to which they finally applied the celebrated appellation of the Fortunate Islands. But the Arabian geographers, Edrisi and Ibn al Vardi, describe, after the Canaries, nine other Islands, situate in the Western Ocean. That these were the Azores is rendered highly probable, by considering, that their number is exactly nine; and that mention is made by these writers of the abundance of a species of eagle or hawk, a circumstance which afterwards appeared to the Portuguese so remarkable, that they derived the name of the Islands from it. The climate in which they are placed also makes them north of the Canaries. Some other coincidences might be pointed out, did our limits permit; and, upon the whole, we see no reason to doubt, that the Azores are really the nine Islands enumerated by the Arabians; though two of the number might probably be Madeira and Porto Santo, while the small Islands of Corvo and Flores might remain unnoticed. The Arabian writers represent them to have been populous, and to have contained cities of some magnitude; but state, that the inhabitants had been greatly reduced by intestine warfare.

The first European discovery of this group is claimed by the Flemings. The Portuguese, eagerly bent upon pursuing their career of navigation along the coast of Africa, did not readily turn into any other direction. A Flemish merchant, called Van der Berg, is reported, in sailing from Lisbon, to have been driven upon these shores. The intelligence soon reached the court of Lisbon, where it excited considerable interest. It is even said that Prince Henry went in person to examine the value of this new discovery. The Islands began, in 1459, to be planted and colonized; and in so fertile a soil, the inhabitants rapidly multiplied. In 1466, Alphonzo V. is said to have granted them to his sister the Duchess of Burgundy; though, in that case, they must have soon reverted to the Portuguese crown. In 1580, they fell, with the other Portuguese territories, under the dominion of Spain. The Azores were at this time the grand rendezvous, in the voyage homewards, of the fleets, which came laden with the wealth of both the Indies. Hence they became a theatre of that maritime warfare, which was carried on with such spirit by the English under Queen Elizabeth against the peninsular powers. In 1586, Sir Walter Ralegh equipped two pinnaces of 35 and 40 tons, the command of which he gave to Captain Whiddon. Having taken two or three prizes, they fell in, off St Michael's, with the great fleet of Spanish galleons, consisting of twenty-four sail, two of them caraks of 1000 or 1200 tons. They attacked them, however, without hesitation, hoping to cut off some straggling member of this great body. It will not surprise our readers, that they were unable to make any impression upon it; but they retired without loss. In 1587, Sir Francis Drake, after having swept the harbour of Cadiz, sailed for the Azores, where he took an East India carak, richly laden, and the first that had ever fallen into the hands of the English. In 1589, the Earl of Cumberland fitted out a squadron, sailed for the Azores, and made numerous prizes.

Under the active administration of Pombal, considerable exertions were made for the improvement of the Azores; but the stupid and bigoted government which followed, rather tended to destroy these benefits, and to make the Islands take a retrograde course.

St Michael.

In giving a description of these Islands, we shall begin with St Michael, the largest and most populous, and the one in which the peculiar physical structure of the Azores is exhibited on the greatest scale. St Michael consists generally of a fertile plain, but diversified by an infinite variety of hills and mountains, all bearing evident marks of volcanic action. The centre of the Island contains chiefly small conic hills; but the east and west quarters rise into lofty mountains, with deep valleys and lakes intervening. The face of the country is almost everywhere smiling; the plains are covered with luxuriant crops; vines and oranges grow on the hills; and even the mountains are adorned with myrtles, laurels, and other evergreen shrubs. All appears a paradise; nor could the observer, at first, suspect that this was a spot chosen, as it were, by nature for the display of all her most terrible phenomena. The form of the mountains, however, soon indicates their history. There are few, which, after being moulded by the volcano, have not been rent by the earthquake. In some cases, the chasm is so complete, that a level path has been formed between the severed members. One of the most remarkable appearance of this kind occurs in the Porto do Ilheo, a small Island about a quarter of a mile from the harbour of Villa Franca. Here a volcanic rock, 2000 feet high, has been completely split, exhibiting a chasm 39 feet wide, from the top to seven feet below the surface of the water. It forms thus, for a few small vessels, a harbour, perfectly safe from every vicissitude of the weather.

In the year 1591, there appears to have been a most tremendous earthquake felt all over the Azores, but which shook St Michael for twelve days without intermission. Since that period, there is no record of any such great convulsion, except one in 1757, of which we have no particulars, and it was probably much less formidable; nor are any of its volcanoes at present in a state of action. Hot springs abound in every part of the Island; and from almost every crevice, vapour is seen issuing. But the most remarkable phenomena are the Caldeiras, or boiling fountains,

Azores.

which rise chiefly from a valley called the Furnas, near the western extremity of the Island. The water ascends in columns, to the height of about twelve feet, after which it dissolves in vapour, forming clouds of various shapes and colours. The heat is such as to boil an egg in two minutes; though the sulphureous impregnation unfits it for being employed in such purposes. The ground in the immediate vicinity is entirely covered with native sulphur, like hoar frost. At a small distance is a remarkable phenomenon, called the Muddy Crater, whose vertex, of forty-five feet diameter, is on a level with the plain. Its contents are in a state of violent and continual ebullition, accompanied with a sound resembling the waves of a tempestuous ocean. Yet it never rises above its level, unless occasionally to throw to a small distance a spray of the consistence of melted lead. The Furnas abound also in hot springs; some of which it is impossible to touch without being scalded. There is almost always, however, a cold spring near to the hot one, so that they can be brought to any temperature that may be desired. These springs, after being long neglected, have, within the last half century, been greatly resorted to, and the cures performed in cases of palsy, rheumatism, and similar maladies, are said to be very wonderful.

St Michael is about 50 miles in length, and varies in breadth from 5 to 12 miles. The plains are fertile in wheat, barley, and Indian corn; while vines and oranges grow luxuriantly on the sides of the mountains. They are made to spring even from the interstices of the volcanic rocks, which are sometimes blasted in order that they may receive the plants. Raised in this manner, they are said to be of superior quality; but the great expence originally required in such a mode of cultivation, confines it to persons of some capital. The western part of the Island yields hemp, which might be raised to a considerable extent. There is also a mountain called *Pico de fer*, which appears to be rich in iron, though no means are at present employed for extracting the ore from it. The exports consist of wine, fruit, and provisions. Foreign intercourse used to be confined rigorously to Lisbon; but since the emigration of the court, the inhabitants have assumed the privilege of trafficking directly with England, America, and other countries. After defraying the expence of its local government, it yields L. 28,000 of revenue to the mother country.

The principal town in the Island is Ponta del Gada, which contains about 12,000 inhabitants. It is built with tolerable regularity, the streets being straight and broad: the religious edifices are numerous and elegant. They consist of two large convents of the orders of St Francis and St Augustin, four convents for professed nuns, and three recolhimentos for such as are not professed. The harbour receives only small vessels. Those of any magnitude must anchor in an open road, which, though not dangerous, cannot be kept during the prevalence of southerly gales. It is, however, the best roadstead in the Island. Ribeira Grande is also a large town on the south coast, containing nearly as many inhabitants as Ponta del Gada. It has two large convents, and there are several warm springs situate in its neighbourhood. Villa Franca, also, though nearly destroyed by the earthquake of 1591, is now a considerable city. Alagoa, Agoa de Pao, Porto Fermoza, and a few others, are also of some magnitude. The whole number of inhabitants in the Island is estimated at 80,000 or 90,000. The character of the people appears to be hospitable, but indolent and luxurious, and they are entirely under the dominion of the priesthood.

St Mary.

St Mary is a small Island immediately adjacent to St Michael's, through the medium of which its trade is conducted, as it has no good harbours of its own. It produces wheat in abundance, and exports a considerable quantity. The soil is composed of clay, which is partly manufactured into pottery.

Tercera.

Tercera, though smaller than St Michael, being placed in a more central position with respect to the other Islands, has been chosen as the seat of Government. The port of Angra is also superior to any of those in St Michael. This Island does not exhibit nearly the same extensive traces of volcanic action: the summits of its mountains are generally level. It is represented by Adanson, however, as entirely composed of volcanic products. Its lava, he says, is of a thicker grain than that of Teneriffe. It abounds in grain and cattle; but its wines are inferior, and its fruits raised merely for internal consumption. The residence of the Government renders the society somewhat superior to that which is found in the other Islands. The number of inhabitants is estimated at 50,000.

Fayal.

Fayal is the most frequented of all the Islands, as its harbour is the best in the Azores, and it lies directly in the track of vessels that are crossing the Atlantic in any direction. The principal town is called Villa de Horta. Captain Cook observes, that all sorts of fresh provisions may be got here; the bullocks and hogs good, but the sheep small and wretchedly poor. The town is defended by two castles and a wall, both in decay, and serving rather for show than strength. The city contains two convents for monks, and three for nuns, with eight churches. These are the only good buildings in it; no other having glass windows. The bay is two miles in length, and three quarters of a mile in breadth, the depth of water from six to twenty fathoms. Though a good road, it is not altogether free from danger in SSW. and SE. winds.

Pico.

A considerable quantity of wine is exported from this place, under the appellation of Fayal wine; but it is really the produce of Pico, one of the most remarkable of the Azores. This Island is composed of an immense conical mountain, rising to the height of 7000 feet, and bearing every trace of volcanic formation. The soil consists entirely of pulverized lava, and the ground has even been said to sound hollow when struck. All the lower parts of the mountain are in the highest state of cultivation, and covered with vine and orange plantations. The wine annually exported amounts to about 5000 pipes. It forms a sort of inferior Madeira, which, selling 50 per cent. cheaper, is in considerable demand. Pico produces also a valuable species of wood, resembling, and equal in quality to, mahogany.

Graciosa and St George.

Graciosa and St George are two small Islands, si-

tuated between Fayal and Tercera. Graciosa is chiefly noted for the extreme beauty of its aspect and scenery. St George has recently been exposed to one of those awful visitations to which the Azores are subject. In 1808 a caldeira, situate in the centre of the Island, was observed to be in a state of violent fermentation. It continued, during several days, to emit subterraneous noises, and to cause violent convulsions through every part of the Island. At length the great crisis came; vast streams of fire issued forth in every direction, with clouds of smoke, which, but for the volcanic light, would have involved every thing in midnight darkness. The principal stream took its direction towards the beautiful town of Ursula, which it seemed on the point of swallowing up; but suddenly changing its direction, rushed into the sea by a different channel,—a happy event, which superstition ascribed to the prayers of the Ursuline nuns. Many hundred acres of fertile land, however, were covered with scoriæ and ashes; some lives were lost, and a general gloom and consternation diffused throughout the Island. The inhabitants, however, showed no disposition to emigrate, and soon applied themselves to repair the damages which their Island had sustained.

Corvo and Flores.

The two small and most westerly Islands of Corvo and Flores, seem but imperfectly to belong to the group. They lie also out of the usual tract of navigators; but to those who, missing their course, are led thither, Flores affords good shelter in its numerous bays. Its poultry is said to be the finest in the world; the cattle are numerous, but small. The surplus produce of these Islands is not of much importance.

It would be improper to close this notice without mentioning one of the most striking occurrences in nature, sometimes exhibited in this quarter—the sudden emersion of new Islands from the bosom of the ocean. The first relation of such an event is given by Kircher in his *Mundus Subterraneus*. He describes it as announced by violent earthquakes, which lasted for eight days; then a fire broke from the surface of the sea, and rose to the clouds; while vast quantities of stones, earth, sand, and minerals, were at the same time vomited out. At length a group of rocks burst forth, which gradually increased till they covered several miles in circumference, and, after being shattered by a new earthquake, settled at length into a solid consistence.

A narrative of a similar phenomenon is given in the 32d Volume of the *Philosophical Transactions*. John Robison, master of a small vessel, is stated to have arrived on the 10th December 1720, at Tercera, "near which Island he saw a fire break out of the sea." On his arrival at Angra, the governor hired his vessel, for the purpose of going to view it. "On the 19th," says he, "at two afternoon, we made an Island all fire and smoke. The ashes fell on our deck like hail and snow. The fire and smoke roared like thunder or great guns." He adds, that quantities of pumice stone (probably common lava), and of half-broiled fish, were found floating on the sea in its vicinity.

A similar phenomenon took place in February 1811, about half a league from the western extremity of the Island of St Michael. It seems to have been attended with nearly the usual symptoms; fire bursting from the sea, and ascending into the air like a host of sky-rockets, accompanied with vast volumes of smoke, and showers of scoriæ and lava. The rocks, however, did not rise above the surface of the water, but appeared immediately under it, with the waves dashing furiously round them. The previous soundings are said to have been eighty fathoms.

On taking a general view of these phenomena, and of the other peculiarities of the Azores, it is impossible not to lament that they should not yet have been surveyed by any scientific observer; and we would fain entertain the hope, that some traveller, properly qualified, may at length be induced to turn his attention to a group of Islands, which, more than any other, seems to offer a rich field of observation and discovery to geologists and naturalists in general.

BAB

BABYLON.—Under this head, in the body of the work, will be found a full account of the extent of ancient Babylon, and of the stupendous edifices, which rendered it the wonder of mankind. Our present object will be, to collect, from recent information, the vestiges which, after so long a succession of ages, still remain, of this celebrated capital of the East.

Among all the remains of ancient grandeur, there are none perhaps which possess equal interest with the ruins of Babylon: none which present so many striking images to the imagination, or carry back the mind into such a depth of antiquity. It happens fortunately that their site, through the learned investigations of Major Rennell, may be considered as completely fixed to the small district, situate immediately to the north of the village called Hellah.* Its po-

* Hellah is nine miles from Mohawil, and nearly forty-eight from Bagdad. Rich's *Memoir on Babylon*.

Babylon. sition on the Euphrates, the fountains of bitumen at Hit or Heet, the distance from the ascertained position of Seleucia and Ctesphion, and the character of the surrounding country, combine in establishing this point beyond a doubt. The appellation *ruins*, in its proper sense, cannot, however, be applied to the present remains of Babylon, which consist almost wholly of bricks, fragments, and rubbish, piled, as it were, in masses, and serving as quarries for the construction of new cities. In this condition, nevertheless, they have deservedly attracted the attention of modern travellers; and interesting notices have been given by Della Valle, Niebuhr, Ives, Otter, and Beauchamp. But the recent observations of Mr Rich, enlightened by the previous inquiries of Major Rennell, have been so much more careful and complete, that they nearly supersede all prior information. We shall first give a view of the objects that presented themselves to Mr Rich, in traversing this celebrated ground, and shall then offer some remarks as to those ancient edifices, of which these objects are to be considered the remains.

Mr Rich commenced his observations at Hellah, and proceeded to the north, along the eastern bank of the Euphrates. After passing some smaller mounds, he came to a vast mass, 1100 yards in length, and 800 in its greatest breadth; while its most elevated part rose 50 or 60 feet above the level of the plain. It consists almost wholly of earth formed from decomposed brick, and strewed with various species of fragments. The name of Amran is given to it from a tradition, seemingly unfounded, of a son of Ali having been buried in it.—Then, after traversing a valley 550 yards long, and crossed by some smaller ruins, he came to the second grand mass, forming nearly a square of 700 yards in length and breadth. This part of the ruins is extremely interesting, containing several walls, in a pretty entire state; they are eight feet thick, in some places ornamented with niches, in others strengthened by pilasters and buttresses. Some remains of painting and sculpture are to be seen on them. The bricks are of the finest kind, and cemented with lime. We may here observe that the city, as Major Rennell suspected, appears to have been built, partly of burnt and partly of unburnt bricks. Three kinds of cement have also been used. The unburnt bricks are in general merely bound together with reeds or chopped straw, which are still found in great quantities. The burnt bricks are cemented, partly with bitumen, but more frequently with lime; a material, the use of which had escaped the notice of observers previous to Mr Rich. He states it to be much the most efficacious of any. Bricks cemented with bitumen could be easily separated; but where good mortar had been used, no power or art could detach them from the wall, without breaking them in pieces. Some parts of the edifice in question have been deeply excavated, with a view to the removal of the bricks; but the workmen have been intimidated, in consequence of the rubbish having fallen in, and buried some of their number; and they have given up the walls, on account of the extreme tenacity with which they are cemented. This edifice is called by the natives the *Kasr* or palace.

A mile to the north of the Kasr, and about half a mile from the river, is a mass equally remarkable. It is an irregular oblong, the sides being respectively 200, 219, 182, and 136 yards in length; the greatest elevation 141 feet. Near the summit of the western side appears a low wall, built of unburnt bricks, cemented with reeds and straw. The summit is covered with heaps of rubbish, and with innumerable fragments of pottery, brick, bitumen, pebbles, vitrified brick, and even shells, bits of glass, and mother of pearl. There are many dens of wild beasts in this part of the ruins, and most of the cavities are filled with bats and owls. As there appeared a niche or recess near the summit of the northern face, Mr Rich caused it to be dug into. The workmen successively extracted two wooden coffins, containing skeletons in high preservation. He was of opinion that the whole passage, whatever might be its extent, would have proved to be occupied in the same manner.

This mass, denominated the *Mujelibé*, being the most elevated part of these remains, has been considered by most travellers as the Tower of Belus, which formed one of the two grand features in the wonders of ancient Babylon. The other was the Palace, with its hanging gardens; and this was clearly pointed out, by ancient authorities, to be on the side opposite to the tower of Belus. The tower then being on the eastern, the palace was to be sought on the western bank of the river. With the exception, however, of a slight notice collected by D'Anville, modern travellers had given no information of any ruins situate in that quarter. Major Rennell very properly pointed out this as a grand object of investigation for future inquirers. Mr Rich, on reaching the summit of the Mujelibé, whence he commanded an extensive view across the river, was much surprised at discovering no trace of any ruins whatever. Not satisfied with this distant view, he crossed and carefully surveyed the ground, but could discern only some mounds of small dimensions, which conveyed no idea of the immense structures of which he was in search. Before leaving this neighbourhood, however, he went to visit a tower, which had been imperfectly observed by Niebuhr, about six miles south-west of Hellah, and beyond the site assigned to ancient Babylon. Our traveller, who had formed no high expectations from this object, was struck with the utmost amazement at its magnitude and grandeur, which decidedly surpassed any thing he had yet witnessed among these interesting remains. It consists of a mound of an oblong figure, 762 yards in circumference. It rises in a conical form to the height of 198 feet, and has on its summit a solid pile of brick 37 feet high, diminishing in thickness to the top. The bricks are of the finest description, with inscriptions on them, and so well cemented with lime, that it is nearly impossible to extract one of them entire. This ruin is called by the Arabs the *Birs Nimrod*. Every thing remarkable is by them ascribed to Nimrod; but the meaning of the term *Birs* seems unknown even to themselves. By the Jews it is called Nebuchadnezzar's Prison. At a trifling distance to the east is a mound equal in elevation to the Kasr; and

Babylon. all around are traces of ruins to a considerable extent.

Mr Rich having thus described these ruins, begins very cautiously to form conjectures respecting their origin and nature. At the first sight of the *Birs Nimrod*, he had involuntarily exclaimed that, if the situation rendered it possible, this certainly must be the tower of Belus. Besides its extraordinary magnitude, there is some appearance of its being built in stages, as described by ancient authors; and the mound on the east may correspond to the temple, which occupied part of the quadrangular inclosure that surrounded the tower. After considering these circumstances, Mr Rich is led on to inquire, whether it be so certain as is generally supposed, that the tower of Belus must be found on the eastern side of the river, and the palace and hanging gardens on the western. But after some acute remarks, his path becomes entangled, and he is obliged to stop, without arriving at any satisfactory appropriation of the objects which had fallen under his observation. The subject is certainly involved in much darkness and uncertainty; but as it is of considerable interest, we shall present our readers with such observations as its consideration has suggested to us.

It is stated by ancient writers, in the most positive and circumstantial manner, that the palace, with its grand appendage of hanging gardens, was situate upon, or very near to the river; whence, indeed, the gardens were artificially watered. Now, modern Babylon presents, near to the river, no ruins of any magnitude, except those on its eastern bank; the Amran, Kasr, and Mujelibé. It seems unquestionable, therefore, that these, if any, must be the remnant of those immense structures. Then, following Herodotus, we must look for the tower of Belus on the western side of the river. But here we are crossed by the statement of Diodorus, to which Mr Rich does not seem to have fully adverted. That author reports, that there were *two* palaces built on opposite sides of the Euphrates; of which by far the most extensive and magnificent was that on the western bank. This Major Rennell naturally infers to be the one which other writers call *the palace*. But it deserves notice, that Diodorus is the only authority for there being *two* palaces. Herodotus and Curtius, the former an eye witness, mention only one, and evidently entertain no idea that any more existed. It seems also quite unaccountable, that, while inferior structures exhibit vast piles of ruins, this western palace, which must have been the grandest and most extensive of all, should not have left the slightest trace of its existence. It may therefore deserve consideration, whether Diodorus, who wrote only from hearsay, might not have been deceived by varying accounts of one palace, into the idea that there were two. The striking similarity in his two descriptions, as to situation, plan, and ornament, somewhat favours the conjecture. We are sensible that it is a bold one; but can only say, that, without it, the aspect of modern Babylon is wholly inexplicable; for it seems quite ascertained, that there are no ruins of any magnitude, close to the river, unless on one side, which is the eastern. It may not be amiss, therefore, to follow out the supposition, and to inquire how far, by its aid, the ancient and the recent descriptions can be brought to accord. Babylon.

Ancient Babylon consisted of an immense square, divided by the Euphrates into two nearly equal parts. It is distinctly stated by Herodotus, that the palace and tower were in opposite divisions to each other. If, then, the ruins on the eastern side be the palace, we must look to the western for the tower. There we find the *Birs Nimrod*, a stupendous pile, the dimensions and character of which are precisely such as the tower, in a state of total dilapidation, might have been expected to exhibit. Yet, to its really being the remains of that edifice, the objections are formidable. First, its distance of nearly ten miles from the Mujelibé would, to include it within the city, require an extension even of the vast limits assigned by Major Rennell. But it is certain, that the extent of Babylon was immense; that it rather resembled an inclosed district than a city. A great part of its area was under cultivation; and it has even been asserted, that the produce raised within the walls could, in case of siege, support its immense population. Without resting on the authority of Herodotus, though it be confirmed by Pliny, even the dimensions of Strabo, reckoned according to his own estimate of the stadium, would give upwards of eleven miles to each side of the square. But it is supposed that the palace and tower must each be in the centre of their respective divisions; an arrangement certainly incompatible with the actual situation of the ruins. The expression of Herodotus, no doubt, is εν μεσω, in the *middle*; which Major Rennell has translated *centre*. We doubt much, however, if this expression can be understood in so precise and mathematical a sense. It is familiarly said, that a building is in the middle or heart of a city, when it is completely inclosed within it, and surrounded by its buildings, even though it may approach to one of its extremities. Such, it appears to us, might be the present meaning, especially since the palace, being upon the river, could not, geometrically speaking, be in the middle of its division. The Kasr above described seems pretty exactly what we should expect in the ornamented and inhabited part of the palace. The Mujelibé, Mr Rich conceives, might be the hanging gardens. We would suggest the mound of Amran as a more probable situation, from its vicinity both to the river and to the palace, while the Mujelibé is at an inconvenient distance from both. This last structure, from Mr Rich's observations, seems decidedly to suggest the idea of a royal sepulchre. Of such structures, several are mentioned in Babylonish history, particularly that of Ninus, said to have been built *within* the palace, and of extraordinary elevation. (Diod. l. ii. 7.)

Mr Rich mentions his intention of making repeated visits to this spot, and of examining the different objects with greater care and minuteness. Additional light may thus certainly be thrown upon the subject, though it seems improbable, after the surveys already made, that any grand feature should remain to be

Babylon || Bacon.

discovered. See *Memoir on the Ruins of Babylon*, by Claudius James Rich, Esq. 8vo. Lond. 1815. (B.)

BACON (JOHN), Academician, born 24th November 1740, who may be considered as the founder of the British School of Sculpture, and whose works are still its greatest boast, was the son of Thomas Bacon, cloth-worker in Southwark, whose forefathers possessed a considerable estate in Somersetshire.

At the age of 14, he was bound apprentice in Mr Crispe's manufactory of porcelain at Lambeth; where he was at first employed in painting the small ornamental pieces of china, but soon attained the distinction of being modeller to the work. The produce of his labour was devoted by him, from his earliest years, towards the support of his parents. While thus engaged, he had an opportunity of seeing the models executed by different sculptors of eminence, which were sent to be burned at an adjoining pottery. An observation of these productions appears to have immediately determined the direction of his genius; and his progress in the imitation of them was no less rapid than his propensity to the pursuit was strong. His ardour and unremitting diligence are best proved by the fact, that the highest premiums given by the Society for the Encouragement of Arts, in those particular classes in which he was a competitor, were adjudged to him nine times between the years 1763 and 1776. During his apprenticeship, he likewise formed the design of working statues in artificial stone, which he afterwards carried to perfection.

Mr Bacon first attempted working in marble about the year 1763; and, during the course of his early efforts in this art, was led, by the resources of his genius, to improve the method of transferring the form of the model to the marble (technically called *getting out the points*), by the invention of a more perfect instrument for this purpose, and which has been since adopted by many sculptors, both in this and other countries.* The advantages which this instrument possesses above those formerly employed, are, its greater certainty and exactness, that it takes a correct measurement in every direction, is contained in so small a compass as not to encumber the workman, and is transferable either to the model or the marble, as may be required, without the necessity of a separate instrument for each.

In the year 1769, the first gold medal given by the Royal Academy was adjudged to Bacon; and in 1770, he was associated by that body. His first work in sculpture was a bust of his present Majesty, George the Third, intended for Christ Church College, Oxford. It is said, that of sixteen different competitions in which he engaged with other artists, he was unsuccessful in one case only. His knowledge of the antique style was for a time called in question; and on occasion of the doubts which were raised on this point, he is reported to have modelled his head of Jupiter Tonans, as the most satisfactory method of repelling the charge. The objection probably originated from the circumstance, that in some of his principal works the figures were represented in the costume of modern times; of which his statue of Justice Blackstone at All Souls College, Oxford, and that of Howard in St Paul's Cathedral, are remarkable examples. But his genius was not subjected to the trammels of this or any one style exclusively. Many of his emblematical figures are designed after the purest models, and in a taste altogether classical. Among others of this character, the monument to Mrs Draper, in the Cathedral of Bristol, is exquisitely simple. In his later productions, likewise, particularly those of a monumental kind, he introduced frequent examples of the ancient style: as in the well known monument to the Earl of Chatham in Westminster Abbey, that to Lord Robert Manners, and others which might be mentioned. "Another marble, scarcely finished at the time of his death," says Dallaway, in his *Anecdotes of the Arts in England*, "will secure him a lasting fame for originality and classical taste. It is the Coenotaph lately erected at Westminster Abbey to the poet Mason. A muse, holding his profile on a medallion, reclines on an antique altar, on which are sculptured, in relief, a lyre, the tragic masque, and laurel wreath; all of the most correct form, as seen on ancient sarcophagi of the pure ages."

Bacon.

On the 4th of August 1779, Mr Bacon was suddenly attacked with an inflammation of the bowels, which occasioned his death in little more than two days. He died in his 59th year, leaving a widow, his second wife, and a family of six sons and three daughters.

Of his merit as a statuary, the universal and established reputation of his works has afforded the decisive proof. "The works of Bacon, Bankes, Nollekins, Wilton, and Flaxman," says Dallaway (and to these might now perhaps be added other names of nearly equal promise), "will rescue the present age from being totally indebted to foreigners for perfection in statuary. His present Majesty, at Christ Church, a bust by the first mentioned, has the strength of Bernini." The various productions of this artist which adorn St Paul's Cathedral, Christ Church, and Pembroke Colleges, Oxford, the Abbey Church at Bath, and Bristol Cathedral, give ample testimony to his powers; above all, those great and prominent works among the monuments in Westminster Abbey.

But it was not as an artist only that Mr Bacon was esteemed. He was no less distinguished by the firmness of his mind, and the uprightness of his private character. His principles were deeply founded, and the virtues which he strove to attain were measured by a standard more unbending than the mere dictates of feeling or of a cultivated taste. He was an avowed believer in the truths of the Christian religion; and in him this belief exhibited its corresponding effects, by producing a consistent influence upon his whole character and conduct. In this manner, the strength of his principles, and the reality of his conviction, were daily manifested throughout

* The invention has sometimes been erroneously ascribed to Mons. Hudon, a French Sculptor.

his life; than which, no test of sincerity is more unequivocal, no instruction more useful, and no recommendation more persuasive.

Mr Bacon was remarkable for the simplicity of his manners, and was, in all things, devoid of ostentation. Of the general powers of his mind, and particularly of his acute and just perception in matters of taste connected with his art, a very favourable opinion will be formed by those who peruse the article SCULPTURE, which he contributed to Dr Rees's edition of Chambers's *Dictionary*.

See *Memoir of the late John Bacon*, R. A. By the Reverend Richard Cecil. London, 1811.—(EE.)

BAKING

Is the art of making *bread*, by which term is meant *loaf-bread*, which is white, soft, full of cavities, has an agreeable taste, and is easily digested.

History of the Art.

1. Like most of the arts of primary importance, its origin precedes the period of history, and is involved in the obscurity of the early ages of the world. There is no evidence from Scripture that Abraham was acquainted with the method of making loaf-bread. Cakes and unleavened bread are repeatedly mentioned as made by him, but no notice is taken of loaf-bread. We are certain that it was known in the time of Moses, as in the Jewish law there is a prohibition to make use of it during the celebration of the passover (Exodus, chap. xii. verse 15). Egypt, both from the nature of the country and the early period of its civilization, seems very likely to have been the place where this art was first practised. The Chaldeans, however, put in a claim. They were civilized nearly as early as the Egyptians, and they were celebrated among the ancients for the goodness of their bread. The Greeks assure us that they were taught the art of making bread by the God Pan. This lively and superstitious people ascribed almost all the important arts of common life to their gods; or rather, perhaps, their gratitude induced them to deify the authors of these most useful inventions. Bakers were unknown in Rome till the year of the city 580, or about 200 years before the commencement of the Christian era. They settled in that city during the war with Perseus, king of Macedon (Plinii *Hist. Nat.* xviii. 11). It was then that the Romans became acquainted with the refinements of the Greeks, and that their capital became crowded with adventurers of all kinds, with artists and philosophers, from the prolific soil of Achaia. Before this period, the Romans were often distinguished or reproached by the appellation of the *pulse-eating nation*.

Since the introduction of bakers into Rome, the art of making bread has always been practised in the south of Europe. But it made its way into the north very slowly; and even at present in the northern countries of Europe and Asia, loaf-bread is seldom used except by the higher classes of inhabitants. In Sweden, for example, you see rolls frequently in the towns, but never loaves. Göttenburgh is a town containing about 23,000 inhabitants. In the year 1812 it was crowded with merchants from all parts of Europe, being the great connecting link between Britain and the Continent. Towards the end of that year, the captain of an English packet ordered a Göttenburgh baker to bake for him a quantity of bread, amounting to L.1 Sterling in value. The baker was confounded at so great an order, and refused to comply, till the captain gave him security that he would carry off and pay for the loaves; declaring that he could never dispose of so great a quantity of bread in Göttenburgh if it were left upon his hand. In the country part of Sweden, you meet with nothing but rye-cakes, as hard nearly as flint, and which are only baked twice a-year. About thirty years ago, loaf-bread was almost as rare in the country places and villages of Scotland, *barley bannocks* and *oaten cakes* constituting the universal substitutes almost among all ranks. But the case is wonderfully altered at present. At that time no wheat was raised in the fertile valley of Strathearn; and the village of Crieff, the largest village in that valley, with a population of nearly 3000 persons, contained only two bakers, who could scarcely find employment. At present it contains five or six, and each has a brisk trade.

In many parts of England, it is the custom for private families to bake their own bread. This is particularly the case in Kent, and in some parts of Lancashire. In the year 1804 the town of Manchester, with a population of about 90,000 persons, did not contain a single public baker. We do not know whether or not it contains any at present.

Different kinds of Wheat Flour.

2. The only substance adapted for making loaf-bread is the flour of wheat, a grassy plant, distinguished among botanists by the name of *triticum*. This plant is cultivated, perhaps, over a greater extent of the globe than any other, and, like man, it seems to adapt itself to almost every climate. We have seen excellent crops of it raised in north latitude 60°. It is cultivated in the East Indies, considerably within the limits of the torrid zone; and, in the north of Indostan, it constitutes a chief article in the food of the inhabitants. The original *habitat* of this plant is unknown. We know, however, that it improves considerably in its quality as we advance south. The wheat of Essex and Kent brings a much higher price than the wheat raised in East-Lothian and Berwickshire. French wheat is superior to that of England. The Italians have the superiority over the French in their wheaten crops, and perhaps the best wheat of all is raised in Barbary and Egypt. Mr Bruce found wheat growing wild in Abyssinia, and, in his opinion, that kingdom is the native country of the plant. It would seem to be originally an African plant, since it thrives best in Barbary and Egypt; and perhaps the mountains of Abyssinia, though within the torrid zone, may not differ much in point of climate from the more northern plains of Egypt. In India the plant seems to have deteriorated. It is always dwarfish, and the crop, we have been

Baking.

told, is less abundant than in more northern climates.

3. The culture of the different varieties of wheat, as practised in this country, and the method of grinding and fitting the flour for the baker, being foreign to the present subject, we cannot, with propriety, touch upon them. It may be sufficient to say, that originally, in England, the baker was his own manufacturer. He purchased his own wheat, and got it ground as he wanted it. At that period, the miller separated the wheat into three portions; namely, flour, pollard, and bran. The bran was the outside of the grain. It was not used as food at all, or only given to horses. The *pollard* was the portion of the grain next the husk; it was coarser and darker coloured than the *flour*, which constituted the interior or central portion of the grain. This flour, at an average, amounted to three-fourths of the wheat ground. But, by insensible degrees, the manufacture of bread became separated into two distinct employments, that of the mealman, who ground the wheat and sold the flour, and that of the baker, who converted it into bread. The mealman made different kinds of flour, some extremely fine and white, while others were very coarse and unpalatable. This white flour, when made into bread, was so pleasing to the eye and the taste, that it gradually got into general use, and the people refused to purchase the bread made of the whole of the flour. At present, in the mills in the neighbourhood of London, wheat is divided into no fewer than seven distinct kinds of flour. The following are the average proportions of these obtained from a quarter of wheat:

Fine flour -	5 bushels,	3 pecks.
Seconds -	0	2
Fine middlings	0	1
Coarse middlings	0	0.5
Bran -	3	0
Twentypenny -	3	0
Pollard -	2	0
	14	2.5

Thus we see that wheat almost doubles in bulk by being ground into flour.

During the bolting of the wheat, there is a fine white gritty substance, called *sharps*, obtained. It constitutes the centre and finest part of the grain of wheat. This is partly sold to the biscuit-makers, and is employed in baking the finest kind of sea-biscuit. It is partly ground again, and constitutes the finest and most valuable kind of flour.

Different kinds of Bread.

4. The bakers in Great Britain, at present, are restricted by act of Parliament to bake only three kinds of bread, namely, *wheaten*, *standard wheaten*, and *household*. The first must be marked with a W, the second with S W, and the third with H; and the baker who neglects to mark them in this manner is liable to a penalty. The wheaten loaf is made of the finest flour, the standard wheaten of the whole flour mixed together, and the household of the coarser flour. The loaves baked are usually peck loaves, half peck, and quartern loaves; the weights of which, provided they be weighed within forty-eight hours of the time of baking, must be as follows:

	lbs.	*oz.*	*dr.* *Avoirdupois.*
Peck loaf	17	6	0
Half peck	8	11	0
Quartern	4	5	8

Before these loaves are put into the oven, they weigh,

	lbs.	*oz.*
Peck loaf	19	12
Half peck	9	14
Quartern	4	15

From this it appears, that the average loss of the quartern loaf in weight by baking is $9\frac{1}{2}$ ounce, or not quite so much as one-seventh of the whole. From the experiments of Tillet, and the other French commissioners who were appointed to examine the subject in 1783 (in consequence of an opinion prevailing in Paris that the bakers did not give the full weight, while these tradesmen declared that they put the proper quantity of flour in the loaves), it appears that the French loaf loses a considerably greater weight in the oven. A loaf which, when put into the oven, weighed 4.625 lbs. when taken out of the oven, weighed at an average only 3.813 lbs. or 0.812 lb. less than at first. This amounts to somewhat more than one-sixth, or very nearly to $\frac{10}{56}$ths of the whole. This greater loss is chiefly owing to the difference between the shape of the English and French loaf. The English has nearly a cubic form, while the French loaf is very long and slender. For it is obvious, that the loaf which presents the greatest surface must lose most weight in the oven.

The French commissioners, however, found that this loss of weight was by no means uniform, even with respect to those loaves which were in the oven at the same time, of the same shape, in the same place, and which were put in and taken out at the same instant. The greatest difference in these circumstances amounted to 0.2889 or 7.5 parts in the hundred, which is about $\frac{1}{13}$th part of the whole. According to this rate, we may suppose that an English quartern loaf, when taken out of the oven, may vary in weight $\frac{1}{13}$th part, which amounts to rather more than $4\frac{1}{2}$ ounces. So that the law which subjects the baker to a penalty if his bread weighs one ounce less than it ought to do, seems too severe, and must have a tendency to injure the goodness of the bread, by making the baker more solicitous about the weight than the quality of his loaf. To this we ascribe in part the badness of the London bread in general, compared with the bread in other places, particularly in Edinburgh, where it is remarkably good. But there are other causes for this deterioration of the London bread, which we believe to be of recent date. These we shall notice hereafter.

Number of Loaves in a Sack.

5. A sack of flour weighing 280 lbs. and containing five bushels, is supposed capable of being baked into 80 loaves in the acts of Parliament regulating the assize upon bread. According to this estimate, $\frac{1}{5}$th of the loaf consists of water and salt, the remaining $\frac{4}{5}$ths of flour. But the fact is, that the number of quartern loaves that can be made from a sack of

Baking.

flour, depends entirely on the goodness of that article. Good flour requires more water than bad flour, and old flour than new flour. Sometimes 82, 83, or even 86 loaves may be made out of a sack, sometimes scarcely 80.

Process of baking.

6. Let us now proceed to give a short description of the mode of baking as practised in Great Britain.

The bakehouse ought to be a large room. On one side should be erected a dresser with suitable shelves above it; on another side a kneading-trough, about seven feet long, three feet high, two feet and a half broad at top, and nineteen inches at bottom, with a sluice-board to pen the dough up at one end, and a lid to shut down like that of a box. On a third side should be a copper, capable of holding three or four pailful of water, with a fire-place to warm the liquid. The oven of course occupies the fourth side. It is a square apartment about three or four feet high, with an arched circular roof, and a brick or stone floor, and furnished with a door which may be shut close. It is the general custom to heat the oven with wood, either faggots or brushwood; but it would be much more economical and cleanly to employ pit-coal for that purpose. The requisite fire-place should be erected at one side of the oven, and the heat may be easily communicated by making the flue wind round the oven. This fire may also be employed to heat the copper and the water in it, which would save an additional fire, or spare the baker the disagreeable necessity of heating the copper in the oven itself, which is pretty generally practised in London. We are persuaded that an oven, constructed upon this principle, would save the baker a considerable annual expence, which, for many years past, has been continually increasing. Indeed, it is obvious that the price of wood must keep pace with the augmentation of the population and wealth of the country.

The temperature to which the oven must be raised to fit it for baking bread is 450°. *(Encyclop. Method. Arts et Metiers,* I. 275.*)* The bakers do not employ a thermometer; but they reckon the oven sufficiently heated, when flour thrown on the floor of it becomes black very soon without taking fire.

Let us suppose that a baker is going to convert a sack of flour into loaves. He pours the flour into the kneading-trough, and then sifts it through a fine wire sieve, which makes it lie very light, and serves to separate any impurities with which the flour may be mixed. An ounce of alum* is then dissolved over the fire in a tin pot, and the solution poured into a large tub, called by bakers *the seasoning-tub.* Four pounds and a half of salt are likewise put into the tub, and a pailful of hot-water. When this mixture has cooled down to the temperature of 84°, three English pints of yeast are added; the whole is well mixed together, strained through the seasoning sieve, emptied into a hole in the flour, and mixed up with the requisite portion of it to the consistence of a thick batter. Some dry flour is then sprinkled over the top, and it is covered up with cloths. This operation is called in London *setting quarter-sponge.*

In this situation it is left about three hours. It gradually swells and breaks through the dry flour scattered on its surface. An additional pailful of warm water is now added, and the dough is made up into a paste as before; the whole is then covered up. This is called *setting half-sponge.* In this situation it is left about five hours.

Three pailfuls of warm water are now added; the whole is intimately blended and kneaded upwards of an hour. The dough is then cut in pieces with a knife, thrown over the sluice-board, and penned to one side of the trough. Some dry flour is sprinkled over it, and it is left in this state for four hours. It is then kneaded again for half-an-hour. The dough is now cut into pieces, and weighed in order to furnish the requisite quantity for each loaf; four pounds fifteen ounces being allowed for every quartern loaf. The method of moulding the dough into a loaf can scarcely be described, and can only be learned by ocular inspection. The loaves are left in the oven about two hours and a half. When taken out, they are carefully covered up, to prevent as much as possible the loss of weight.

The above description applies only to the mode of baking as practised in London. No doubt, slight differences exist in different countries. The French loaf, which is baked in a pan, requires obviously a different process from the English loaf, and it is kept a longer time in the oven.

Alum is not added by all bakers. The writer of this article has been assured by several bakers of respectability, both in Edinburgh and Glasgow, on whose testimony he relies, and who made excellent bread, that they never employed any alum. The reason for adding it, given by the London bakers, is, that it renders the bread whiter, and enables them to separate readily the loaves from each other. This addition has been alleged by medical men, and is considered by the community at large, as injurious to the health by occasioning constipation. But if we consider the small quantity of this salt added by the baker, not quite $5\frac{1}{2}$ grains to a quartern loaf, we will not readily admit these allegations. Suppose an individual to eat the seventh part of a quartern loaf a-day, he would only swallow eight-tenths of a grain of alum, or, in reality, not quite so much as half a grain; for one-half of this salt consists of water. It seems absurd to suppose that half a grain of alum, swallowed at different times during the course of a day, should occasion constipation.

Use of Yeast in Baking.

7. The addition of the yeast of beer to make the dough swell is an improvement of the original practice. *Leaven* was used by the ancients for this purpose. Hence we read in the Old Testament of *unleavened bread,* as distinguished from *loaf-bread.*

---

* In London, where the goodness of bread is estimated entirely by its whiteness, it is usual with those bakers who employ flour of an inferior quality, to add as much alum as common salt to the dough. Or, in other words, the quantity of salt added is diminished one-half, and the deficiency supplied by an equal weight of alum. This improves the look of the bread very much, rendering it much whiter and firmer.

Baking.

The method of baking by means of leaven was this: A quantity of flour is made up into dough with water; this dough being set in a warm place, is left for about thirty-six hours. During that period it swells considerably, and becomes of a thinner consistency. In short, it undergoes a species of fermentation. It has now acquired a peculiar smell, and a disagreeable sour taste, and is the substance known by the name of *leaven.* If this substance be mixed with a quantity of fresh dough, it occasions the whole to undergo a speedy fermentation, and to swell precisely in the same manner as dough mixed with yeast. Bread skilfully baked in this manner is not inferior to yeast bread; but when unskilfully managed, it has a sour taste, and contains a quantity of acetic acid. According to the experiments of Mr Edlin, a pound of flour, when converted into leaven, contains as much acetic acid as requires 40 grains of carbonate of potash to neutralize it. If by carbonate he means (as is probable) *bicarbonate* of potash, 40 grains of it contain 21 grains of potash, which requires for saturation $22\frac{1}{2}$ grains of acetic acid.

Pliny informs us that yeast in his time was employed in Spain and Gaul as a *ferment* of bread. *Galliæ et Hispaniæ frumento in potum resoluto, quibus diximus generibus, spuma ita concreta pro frumento utuntur. Qua de causa levior illis quam cæteris panis est.* (*Natur. Hist.* lib. xviii. c. 7.) From this passage we see that the Romans employed leaven to raise their bread, but that they were sensible of the superiority of yeast. Leaven, however, made its way both into France and Spain, and was universally employed in the manufacture of bread till towards the end of the seventeenth century, when the bakers of Paris began to import yeast from Flanders, and to employ it pretty generally as a substitute for leaven. We have here a striking instance of the blindness and obstinacy of the learned and the powerful, and the readiness with which they are disposed to arm themselves against all alterations and improvements. The bread by this substitution was manifestly improved both in appearance and in flavour. This variation excited attention; the cause was discovered; the faculty of medicine in Paris declared it prejudicial to the health; the French government interfered, and the bakers were prohibited, under a severe penalty, from employing yeast in the manufacture of bread. But it is in vain for governments, colleges, and universities, to oppose themselves to those improvements which take place in the arts and manufactures essential to civilized society. The ingenuity and perseverance of self-interest is proof against prohibitions, and contrives to elude the vigilance of the most active government. The laws of Queen Elizabeth, however tyrannical and absurd, did not prevent the introduction of indigo as a dye-stuff into England. Neither did the authority of Louis the Fourteenth, nor the decision of the physicians, deter the Parisian bakers from persisting in their improved mode of making bread. The yeast in Flanders was put into sacks, the moisture was allowed to drop out, and in this comparatively dry state it was carried to the capital of France.

The superiority of yeast bread became gradually visible to all, the decisions of the medical faculty were forgotten, and the prohibition laws were allowed tacitly to sink into oblivion. The new mode of baking by degrees extended itself to other countries, and is now, we believe, practised everywhere. In warm climates, where the yeast of beer cannot be had, other substitutes are employed, which answer the same purpose. In the East Indies, bread is raised by means of the liquor called *toddy,* which flows out of the cocoa-nut tree when its branches are cut, and which ferments so rapidly, that in two or three hours it becomes an intoxicating liquor. In the West Indies *dunder* is employed for the same purpose. This is the liquid which remains in the still after the rum is distilled off, and is therefore analogous to what our distillers call *spent wash.* It no doubt consists of a solution of unaltered sugar, prevented from fermenting by the alcohol which the liquid contained before distillation, and mixed doubtless with a quantity of yeast. In that warm climate it undergoes a very speedy fermentation, and on that account answers all the purposes of yeast in the baking of bread. In this country it is no uncommon thing to convert the spent wash into small beer, which the workmen drink with avidity. But it only undergoes this change when fermented in the usual way with yeast.

Constituents of Wheat Flour.

8. The appearance of wheat flour is too familiar to every person to require any description here. The ancients knew that it consisted chiefly of a substance called *starch;* which, as Pliny informs us, was first separated from wheat by the inhabitants of the Island of Chio, and in his time the starch of Chio was considered the best and lightest, because it was made from wheat which was not ground. (Plinii *Natur. Hist.* 18. 7.) This is the mode still followed by the manufacturers of starch, and is no doubt the reason why the other constituents of wheat were so long in being discovered. About the year 1728 Beccaria, an Italian philosopher, discovered another constituent of wheat, to which the name of *gluten* has been given. His method of obtaining it was this: He took a quantity of flour, and formed it into dough with water; this dough he kneaded continually between his fingers, while a small stream of water dropt upon it. He continued the kneading as long as the water ran off milky. By this process, the whole of the starch was washed away, and there remained in his hand a grey-coloured, elastic, and very adhesive substance, which was the gluten. (*Collect. Academ. partie Etrang.* 10. 1.) No other grain, besides wheat, contains gluten in any considerable quantity. Traces of it may be discovered in barley. But the gluten of barley cannot be separated by washing. It is obtained by solution in water. For gluten is soluble in a small proportion in cold water. But when that liquid is heated to 120° or 130° the gluten coagulates, and falls down in grey-coloured flocks. By this method gluten may likewise be discovered in the leaves of many trees.

The water employed to wash out the starch soon deposites that substance in the form of a white powder. If this water be now filtered, evaporated to a small quantity, filtered again to separate the coagulated gluten, clarified with white of egg, and then evaporated to the consistence of a syrup, it deposites,

Baking.

according to Mr Edlin, crystals of sugar in four-sided prisms, with dihedral summits. (Edlin *on Bread Making*, page 49.) If this experiment be correct, wheat contains a portion of common sugar. But we have great doubts respecting it. We scarcely believe it possible to obtain in regular crystals the very small quantity of sugar that must be contained in a pound of wheat by the process described by Mr Edlin, for he merely set the syrup aside to crystallize in a cool place. Common sugar thus treated would concrete into a hard mass, but would not crystallize. We believe that wheat flour contains a portion of saccharine matter, but it is a species different from common sugar. We have never, indeed, made any experiments on the sugar of wheat, but we have made a great many on the saccharine matter of barley, which we found similar in its properties to the sugar into which starch is converted by being long boiled in very dilute sulphuric acid. There is every reason to believe that the sugar in wheat is similar to that in barley. Now, the sugar in barley crystallizes in spheres similar to candied honey.

9. Starch, the first, the most important, and by far the most abundant constituent of wheat flour, is a white, crisp, crystalline-like substance, insoluble in cold water, but forming with hot water a thick paste, which has the property of gluing bodies together. If it be roasted on the fire till it assumes a brown colour, it becomes soluble in water, and acquires the properties of gum. If it be boiled for forty-eight hours in water, holding one-hundredth part of its weight of sulphuric acid in solution, it is dissolved and converted into a species of sugar. This sugar is heavier than the starch from which it was formed; the sulphuric acid remains unaltered; and no gaseous body is either absorbed or emitted. Hence it has been concluded, that this sugar is merely a combination of starch and water; and that the acid acts only by promoting the solution of the starch, without which it is incapable of uniting with water. Starch is one of the most nourishing articles of food, and is undoubtedly the portion of the wheat flour that renders bread so nutritive.

10. The gluten, the second constituent of wheat flour, is but small in quantity when compared with the starch. It is a grey substance, exceedingly elastic and adhesive. It is not sensibly soluble in water after it has been collected into an adhesive mass. Nor does it dissolve in alcohol or ether. When dried, it becomes brown and semitransparent, and when thrown on hot coals, emits a smell similar to that of burning horn. If it be put into a vessel, moist, and set in a damp place, it undergoes a species of fermentation. Bubbles of gas separate from it. After some days it becomes of a much thinner consistence, and then may be employed to agglutinate substances together. In about ten days or a fortnight, it acquires exactly the smell and taste of cheese, which it resembles in every thing but the colour, which is too dark. This *caseous* fermentation, if the expression may be permitted, distinguishes gluten from all other vegetable bodies with which we are acquainted. It is to the gluten that wheat flour owes the property of being converted into loaf-bread. All other grains are unfit for that purpose, but they become fit as soon as we add to them a sufficient quantity of gluten, or mix them with wheat flour. In this way barley, potatoes, and even turnips, may be made into very good bread.

11. The sugar is by far the smallest, in proportion, of all the constituents of wheat flour. If it be starch sugar, as we believe it to be, it possesses the following properties: It does not crystallize in prisms like common sugar, but assumes the form of spheres like honey. It is not so hard as common sugar, neither is it so soluble in water. Its sweetening power, according to Kirchhoff, is to that of common sugar as 1 to $2\frac{1}{2}$. But the most distinguishing property is that, when dissolved in water, it ferments of itself, without the addition of any yeast; whereas common sugar does not undergo that process unless yeast be mixed with its aqueous solution. Hence the reason why the dough of wheat flour ferments, and is converted into leaven. This fermentation does not take place if the saccharine matter be washed out of it by water, as Mr Edlin ascertained by direct experiment. The fermentation of wheat flour is at first confined to the saccharine matter. It first undergoes the vinous fermentation; here the process, if possible, ought to be stopped. But as this is usually not possible, the acetous fermentation commences, and vinegar is formed. Probably at last the starch itself is acted on, and occasions the bad taste of ill baked leavened bread, though this is doubtful.

12. As to the proportions of these three constituents, they differ so much in different kinds of wheat flour, that nothing precise on the subject can be determined. The greater the proportion of gluten, the better in all cases is the flour. When the wheat has not fully ripened, or when it has been exposed to rain while lying on the field, the gluten cannot easily be separated from the starch by the process above described; nor does it form an elastic, adhesive mass; but a friable substance, distantly resembling the fibrous matter of potatoes. Hence the goodness of the flour may be determined by the state of the gluten. The writer of this article has repeatedly applied this test to London flour; but he has been always unlucky enough to find it decidedly bad. From the flour furnished by two or three different bakers in different parts of the town, he either was unable to obtain any gluten, or it wanted the adhesiveness which characterizes the gluten of good wheat. No doubt, there must be abundance of excellent flour in London; but we believe (and our opinion is founded on the bread, which, in general, is greatly inferior in goodness to the Edinburgh bread) that a very considerable proportion of the flour used is bad. The inhabitants of London pride themselves on the goodness of their bread; but never was any set of men more mistaken. The London bread is, indeed, whiter; but, in other respects, worse than any we have met with in Great Britain, except the bread baked in Berwick-upon-Tweed, which is very bad, owing entirely to the unskilfulness of the bakers.

To furnish an idea of the proportions of the constituents of flour in good wheat, we shall give the result of an analysis of Mr Edlin's. He separated a pound avoirdupois of wheat into the following ingredients:

	oz.	dr.
Bran	3	0
Starch	10	0
Gluten	0	6
Sugar	0	2
Loss	2	0
Total	16	0

In this case, it appears that the gluten amounted to $\frac{1}{2\text{T}}$ of the whole flour, the sugar was $\frac{1}{64}$th part, the bran $\frac{1}{5}$th, and the starch almost $\frac{2}{3}$ds of the whole flour.

Modes of preparing Yeast.

13. The yeast which is employed to ferment or raise the dough is obtained in London from the brewers of ale. In Edinburgh, the greatest part of the yeast used by the bakers is either prepared by these tradesmen themselves, or procured from those who manufacture yeast on purpose to supply the bakers. Various methods and various ingredients are used for this purpose; but the following method is, we believe, as good as any:

Add ten pounds of flour to two gallons of boiling water: stir it very well into a paste. Let this mixture stand for seven hours, and then add about a quart of yeast. In about six or eight hours, this mixture, if kept in a warm place, will have fermented, and produced as much yeast as will bake an hundred and twenty quartern loaves.

Yeast made in this way answers the purposes of the baker much better than brewers' yeast; because it is clearer, and free from the hop mixture, which sometimes injures the yeast of the brewer. Some years ago, the bakers of London, sensible of the superiority of this artificial yeast, invited a company of manufacturers from Glasgow to establish a manufactory of it in London, and promised to use no other. About L. 5000 accordingly were laid out on buildings and materials, and the manufactory was begun on a considerable scale. The ale brewers, finding their yeast, for which they had drawn a good price, lie heavy on their hands, invited all the journeymen bakers to their cellars, gave them their full of ale, and promised to regale them in that manner every day, provided they would force their masters to take all their yeast from the ale brewers. The journeymen accordingly declared in a body, that they would work no more for their masters unless they gave up taking any more yeast from the new manufactory. The masters were obliged to comply; the new manufactory was stopped, and the inhabitants of London were obliged to continue to eat worse bread; because it was the interest of the ale brewers to sell their yeast. Such is the influence of journeymen bakers in the metropolis of England!

What the substance in yeast is which induces fermentation has not yet been determined. Beer yeast may be dried, and kept in that state for a considerable length of time, and if moistened again with water, it becomes capable of acting as a ferment. If it be washed in alcohol, its fermenting power is destroyed. If it be kept in a moist place, it undergoes a change very similar to the caseous fermentation of gluten. But yeast and gluten are distinct substances; for gluten is incapable of producing the vinous fermentation. Sugar of starch ferments of itself when diluted with water, and the juice of grapes also ferments of its own accord, because it contains a quantity of sugar similar to the sugar of starch.

But as far as baking is concerned, the knowledge of the peculiar substance which occasions fermentation is not material. The only useful purpose which fermentation in dough serves, is to generate a quantity of carbonic acid gas. If the dough be impregnated with this gas by any other method, fermentation is not necessary. Mr Henry of Manchester found, that if flour be kneaded into dough with water saturated with carbonic acid gas, the dough rises as well, and the bread is as light and well tasted as when it is baked with yeast. Hence, those bakers who live near Seltzer water, or any water impregnated with carbonic acid gas, may substitute that liquid for yeast, without injuring the quality of their bread. The quantity of salt contained in a quartern loaf, may be reckoned about an ounce avoirdupois, or 437 grains. If, instead of the ounce of salt, you dissolve in water 2 oz. 5 dr. 45 gr. of the common crystallized carbonate of soda, and mix the solution well with your dough; if you now add 7 oz. 2 dr. 22 gr. of muriatic acid, of the specific gravity of 1.121, and knead it as rapidly as possible with the dough, it will rise immediately, fully as much, if not more, than dough mixed with yeast, and when baked, will constitute a very light and excellent bread.

Panary Fermentation.

14. These examples are sufficient to explain what is called the *panary* fermentation. There is, in fact, no such thing as a fermentation peculiar to bread. But wheat flour contains a portion of saccharine matter, which readily undergoes the vinous fermentation. During this fermentation, carbonic acid gas is evolved in every part of the dough. This gas is prevented from escaping by the gluten, which forms every where through the dough an adhesive web, through which gaseous substances cannot make their way. Hence, the dough swells in every direction, the particles of starch are separated from each other, and by the heat of the oven, they are arrested in that position. So that the loaf, when cut, appears full of round and oblong cavities, each of which in the dough had been filled with a globule of carbonic acid gas. It is to the presence of these cavities that the bread owes its lightness, its agreeable taste, and its easy digestion. Even its colour is owing, in a great measure, to the same cause. For when loaves of wheat flour are baked without the addition of yeast, or the presence of carbonic acid, they constitute one solid, dark-coloured, disagreeable tasted mass, which has been found not only nauseous to the palate, but likewise of difficult digestion. These disagreeable qualities are, in a great measure, obviated by converting the dough into thin cakes, and baking them rapidly on a hot iron plate over the fire. Accordingly, this is the method followed, when wheat flour is converted into bread without fermentation.

Nutritive Qualities of Bread.

Thus then the theory of bread making is completely developed. Nothing can be simpler or more ingenious than the process followed by the baker. Nor ought the wonderful composition of wheat flour, which adapts it so well for the manufacture of bread, to be passed over in silence. Without the presence of the saccharine matter, the fermentation could not

be produced in it, carbonic acid gas would not be evolved, and the bread would be hard, heavy, black, and difficultly digestible. Without the presence of the gluten, the carbonic acid would make its escape as soon as formed, and the advantages of the fermentation would be lost. And, finally, without the presence of the starch in such a notable proportion, the bread would neither be a palatable nor a nourishing article of food. It has been supposed, indeed, that the gluten is the substance which renders bread so nourishing. But we conceive this to be a mistake. In the first place, its quantity, when compared with that of the starch, is trifling. And, in the second place, we know from other circumstances, that starch is peculiarly fitted for being the food of animals. Nearly one-half of the human race live almost wholly on rice, a grain which consists almost entirely of starch; and the small quantity of that grain which constitutes the daily food of an inhabitant of Indostan, and which supports his life, is truly astonishing.

Potatoe Bread.

15. As no other grain except wheat flour contains these three constituents, in the requisite proportions, it would be in vain to attempt to convert them into bread, by the same process as is followed by the baker in making wheaten bread. Potatoes, for example, contain no sensible quantity of saccharine matter. It would be in vain, therefore, to expect them to ferment, like wheat dough, when mixed with yeast. But we have little doubt, that mashed potatoes might be made into very good bread, if they were kneaded with water impregnated with carbonic acid gas, or still better, if, instead of common salt, the constituents of that substance were added in the proper proportions, as they have been already given in this article. Potatoes contain a very great proportion of water, and when boiled in water, they communicate a brown colour, and give the liquid a disagreeable taste and smell.

It is proper that this substance, which some have considered as of a poisonous nature, should be previously removed. Einhof has given us the following substances as the constituents which he found in potatoes:

Water - -	72.6
Starch - -	15.0
Fibrous matter -	7.0
Albumen - -	1.4
Mucilage - -	4.0
	100.0

Dr Pearson's analysis is somewhat similar; only he obtained a greater proportion of water. Einhof found both tartaric and phosphoric acid in potatoes. The fibrous matter in potatoes seems to be a peculiar modification of starch It supplies the place of the gluten in wheat flour, and gives to the paste of potatoes considerable stiffness and adhesiveness. It is upon these properties that we found our opinion, that if the paste of potatoes were properly impregnated with carbonic acid gas, it would make a good-looking and well tasted loaf. There is, however, the less occasion for this attempt, as potatoes, when properly boiled, constitute an agreeable substitute for bread, without any farther preparation. When made into bread, they are always mixed with wheat flour. A mixture of two parts flour, and one potatoes, makes an agreeable bread, which cannot be distinguished from wheaten bread. The starch of potatoes is remarkably beautiful, and goes farther than wheat starch. We have been assured, that what is sold in the shops under the name of Indian arrow root, is nothing else than potatoe starch mixed with a little gum tragacanth. It is well known what an agreeable food this preparation is capable of furnishing.

Rye Bread.

Rye is very much used as an article of food in northern countries. In Sweden it constitutes almost the only bread of the common people not baked in loaves; but made up into cakes, which are usually as hard as wood. When baked into loaves, it has a brown colour and a sweetish taste, which gives it a considerable resemblance to gingerbread. Rye, according to the analysis of Einhof, is composed of the following constituents:

Albumen - -	3.27
Moist gluten - -	9.48
Mucilage - -	11.09
Starch - -	61.09
Saccharine matter	3.27
Husk - -	6.38
Moisture - -	5.42
	100.00

The saccharine matter present in this grain is probably sufficient to cause it to undergo fermentation. But the proportion of gluten is very small; probably not amounting to 3 *per cent.* Accordingly, when rye flour is washed in water, the whole of the gluten is dissolved in that liquid. Hence it is obvious, that, in order to make good rye bread, it ought to be mixed with a quantity of wheat flour. This kind of bread is very much used in the counties of Northumberland and Durham, and we have no doubt that it is both palatable and nourishing. Certainly it is very far superior to the rye cakes, used by the peasants in Sweden.

We have been told that rice flour may be made into loaf-bread. But we have never had an opportunity of seeing these loaves, and do not know how far they resemble those of wheat flour. Rice has never been subjected to chemical analysis. We do not know, therefore, what its constituents are; though there is every reason, from its properties, to consider it as almost entirely composed of starch.

Assize of Bread, and State of the Bread trade in London.

16. Having now given a description of the method of baking bread, and explained the nature of the process, we might here conclude this article. But it may be of some utility, if we give a short statement of the principal laws which have been enacted in Great Britain respecting bread, and if we endeavour to lay before the public the present state of the bread trade in London, and explain the abuses and frauds that are practised by those concerned in it in that capital. We despair of seeing these abuses rectified; but it is a great point at least to make them known.

In the period of English history, between the Norman conquest and the reign of Edward the First, the price of wheat fluctuated enormously. Thus, in the

Baking.

43d year of Henry the Third, it was sold for 20s., or 60s. of our money, a quarter. Multitudes of poor people were forced to live upon the bark of trees, and upon horse-flesh, and above twenty thousand died in London of famine. In the same reign, as appears from the statutes, the price of wheat was as low as 1s. a quarter. These prodigious fluctuations show the little communication at that time existing between the different countries of Europe. Farming must have been in a very low state in England. When wheat was very cheap, the farmer could not dispose of his crop, which lay rotting on his hands. When it was dear, there was such a scarcity, that he could hardly procure seed for sowing his fields, or was unable to afford money to purchase it.

It was conceived, that these evils would be, in a great measure, remedied by fixing the price of bread, which was accordingly done by a proclamation of King John. This absurd innovation being found ineffectual, it was repealed by the *statute of assize*, enacted in the 51st year of Henry the Third, *anno Domini* 1267. By this law, the price of bread was regulated by the price of wheat, and the baker was allowed 7¼d. for baking a quarter of wheat, and furnishing salt and the other ingredients which are added to bread; besides the profit which accrued from the additional loaves made from a quarter of wheat beyond what the statute allows. This money allowance was gradually augmented to the baker in different reigns, according to the following statement:

		s.	*d.*
Edward I.	to	1	1
Henry VII.		2	7
Elizabeth		6	10
Elizabeth		6	0
Anne		12	0
George II.		15	6
George III.		14	0

This last regulation took place in the year 1798. By this act, the magistrates were enjoined to set the assize from a sack of flour, instead of a quarter of wheat, and to allow the baker 11s. and 8d. for his expences. The new duty on salt, during the French revolutionary war, raised this sum to 12s. at which it continued. By the act of Parliament, the baker was supposed to make 80 quartern loaves from the sack of flour; whatever greater number the sack produced was so much more profit to the baker.

Very particular laws were enacted, obliging the corn-factors to give in the quantities and prices of the flour sold, and the bakers the quantities and prices at which they bought it. Penalties were enacted to prevent false returns, to prevent adulterations and improper combinations between the bakers, or the corn-factors and bakers. The weight of the loaf was determined, and all loaves deficient in weight one ounce, or not marked with the letters W, S W, H, according to the quality of the bread, may be seized; and the baker, besides the loss of his bread, is subjected to a penalty. These laws are so numerous, and so minute, that it would be tedious to copy them. Nothing more would be learned from them but the amount of the penalty for each offence, varying from L.50 to 1s., according to the supposed enormity of the transgression. It is the business of the magistrates in towns, and of justices of the peace in the country, to regulate the assize, and the price of bread is determined by the price of wheat, according to a table given in one of the acts. When that price varies 6s. the quarter, then the price of the loaf is varied one assize, or a halfpenny the quartern loaf. Magistrates likewise may alter the price of the loaf half an assize, or a farthing in the quartern loaf.

Whoever considers the indecent way in which oaths are administered in English courts (for it is upon the oaths of the bakers and corn-factors that the acts depend for the accuracy of the returns), and the little regard paid to them by merchants and manufacturers, partly in consequence of this indecency, partly in consequence of their multiplicity, and partly on account of the many absurd impediments that the Legislature has thrown in the way of merchants and manufacturers—whoever considers these things, will be at no loss to conclude, that all these checks, and penalties, and oaths, have entirely failed in producing the intended effects. In London, where the number of bakers is great, and the competition in consequence ought to ensure the best bread at the lowest possible price, the bread laws, by making the prices of all bakers the same, have destroyed this competition, have formed the bakers into a regular company, having occasional meetings to consult their peculiar interests, and have raised in them a spirit of honour, which makes them to consider it as unhandsome to undersell their neighbours. The price of flour is easily regulated between the bakers and the corn-factors, the consequence of which regulation is, that the quartern loaf is always 2d. dearer than in any other part of Great Britain. The reason assigned is, that the finest flour only is employed in London, and that the London bread is better than any other. The writer of this article is well aware of the contrary. The London bread is, in his opinion, nearly the worst bread in Great Britain; and the flour is greatly inferior to what is used by the bakers in Edinburgh. He has frequently examined flour purchased from bakers in both cities, and the Edinburgh flour, except in bad years, when the crop had been injured, was uniformly superior in quality to the London flour.

The magistrates of London have at last become sensible of the truth of these facts; and that the Government, by their officious interference, and their minute enactments, have injured instead of improved the quality of the bread. They have, in consequence, applied to Parliament, and by their influence, the assize on bread, as far as it affects London and its environs, has been taken off. But the good effects expected have not yet resulted from this judicious measure. The spirit of monopoly has been sunk so deep into the minds of the bakers by the assize laws, that some time must elapse before it be eradicated. It is said that they have a weekly meeting, and settle the assize privately in the same manner as it was before publicly done by the Lord Mayor and Aldermen of London. But this *esprit de corps* cannot continue very long. Where there are 1600 ba-

kers, as in London and Westminster, it is not consistent with the nature of things to suppose that they can long continue united, so as to act only together, and by concert. Self-interest will induce first one individual, and then another, to consult his own private advantage, and to endeavour to secure an increase of business by underselling his neighbours. The bond will thus be broken asunder, and every one will be obliged to serve the community at the lowest possible rate.

It is a pity that the Legislature would not see that the same liberty which has been given to the baker, ought to be extended to the corn trade in general. The depreciation of money, which was the consequence of the unnatural state into which Europe was brought by the French revolution, our almost total seclusion from the Continent, and a series of bad crops for several years, raised the price of corn in this country to an enormous height. The landlords took advantage of this increase to raise the rents, while Government loaded the farmer with heavy taxes. But in a state of peace, and supposing the seasons to be tolerably favourable, the prices cannot be kept up. The landed proprietors, indeed, conceived, that corn could be continued in this country at its unnatural height, simply by prohibiting the importation of foreign corn. It was with this view that the corn-bill was brought into Parliament, and carried last year (1815) by a great majority, notwithstanding the almost universal expression of the inhabitants of Great Britain against the measure. These legislators did not consider that the average deficiency of corn in Great Britain does not amount to a week's consumption: that though they may prevent corn from being imported into Great Britain, they cannot prevent such of the inhabitants as choose it from going to those places where corn is cheap. The corn-bill will not have the effect of keeping up the price of corn; but it will act as an encourager of emigration. Suppose the population of Great Britain to be 12,000,000, the emigration of 100,000 inhabitants would probably be sufficient to prevent the necessity of importing corn. Perhaps a smaller number would be sufficient, as those who will be obliged to emigrate are chiefly families with small fortunes, who may be supposed to consume more wheaten bread than the very lowest of the people. The hardships of the farmer cannot be alleviated in any other manner than by lowering his rent, and easing him of his oppressive taxes.

17. About sixty years ago, the dealers in corn in London carried on their business at Bear Quay; but, this situation being very inconvenient, the Corn Exchange in Mark Lane was erected by a company of proprietors for the accommodation of the factors and dealers. Seventy-two stands were allotted on which the samples of corn are exposed to sale. Sixty-four of these stands are let out on lease to factors or dealers, and the remaining eight are appropriated to the use of the Kentish hoymen. "Although the Corn Exchange is considered as open to all who come to buy and sell, yet no person can carry on the business of a corn-factor, to any considerable extent, unless he is in possession of one of these stands. Here the factors are at liberty, either to expose all their samples at the same time, or as few of them as they think fit: so that a buyer has no means whatever of judging, from the appearance of the samples exposed on the stands, during any period of the market, what the supply is, or what quantities of corn are imported, coastwise, or from abroad." *(Report of the Committee of the House of Commons respecting Corn.)*

Here the millers, mealmen, and corn-chandlers, transact their business with the corn-factor, and not with the seller. These men purchase the wheat, carry it down to Essex and other counties, convert it into flour, and bring it back to London to supply the bakers. The profits of the baker are but small, supposing him to carry on his trade without any fraud. Let us suppose him to bake 12 sacks a-week, which, from the evidence of the bakers examined before the Committee of the House of Commons, seems to be a fair average. They are allowed 12s. for each sack, which amounts in the week to L. 7. Let us suppose farther, that every sack yields 82 loaves instead of 80, so that they have a profit of two loaves on each sack. This, when the quartern loaf is at 10d., will amount to L. 1 more. Let us suppose farther, that the puddings, pyes, and meat, which they bake, will defray the expence of their fuel. By this statement, their weekly income will be L. 8. Out of this they have to pay for salt and yeast, and likewise their journeymen's wages. Now, L. 4 seems as little as can well be allowed for these purposes. According to this statement, L. 208 a-year seems to be the amount of an ordinary baker's income in London, supposing him not to practise any fraud.

The consequence of this small profit is, that men of capital seldom embark in the trade. The bakers in London are mostly poor men, who begin the world without any capital; and in consequence of the great competition, are never able to deal so extensively as to acquire one. It is scarcely necessary to observe what must be the consequence of this. They are at the mercy of the mealmen, who supply them with flour as they think proper, of what quality they think proper, and at what price they think proper. Hence the high price and the badness of the London bread. The profits go all into the pockets of the mealmen, who keep the bakers in a state of comparative slavery, and oblige the inhabitants of London to eat the worst and the dearest bread in Great Britain.

Some ingenious bakers in London, in order to make up for the smallness of their profits, have hit upon the plan of mixing potatoes with their flour, and we are credibly informed, that not less than 300 tun of potatoes are consumed for this purpose every week. Perhaps the quality of the bread is not much injured by this practice; for some of the bakers most in repute employ potatoes to a considerable extent, and the consumption of wheat is very materially diminished by it. But the grievance is, that the same price is taken for a potatoe loaf as for a loaf of the finest wheaten flour, though it must cost the baker much less. (J.)

The reader will find some account of the substitutes which have been proposed for wheat flour, in seasons of scarcity, under the article BREAD in the *Encyclopædia*.

BALANCE OF POWER,

Among States, a most important object of foreign policy, intimately connected with the general peace and independence of nations; but which some have strangely treated as altogether chimerical, and others as strangely represented as having led only to pernicious results. It is far more generally admitted, however, to have a real foundation in the principles of intercourse and union among states, and to have exercised a great and beneficial influence on the affairs of modern Europe. We say of modern Europe, because, though the policy in question was not wholly unknown to other ages and countries, it was no where *systematically* pursued, but among the nations of this quarter of the world. Previous to the sixteenth century, there was little political connection among those nations, their circumstances not being such as to admit of any regulated attention to foreign affairs; but about the commencement of that century, Europe began to be formed into one grand community or federal league, of which the actuating principle was the preservation of the balance of power. The attention to this principle thenceforth influenced all the great wars and negotiations, and made every foreign movement, however remote, an object of interest and interference throughout every part of the system.

We shall endeavour to sketch a general outline of this important subject; and, in doing so, we shall notice, though in a brief way, all the principal topics which it seems to us to present for discussion. The references which we shall frequently make to other writers, will serve both to illustrate and support our own views, and to point out the sources of more profound and complete information than we have either ability or room to give in this sketch.

General Idea of a Balance of Power, and of the System founded on it.

I. The ultimate intention of the system founded on a balance of power, is to secure every state in the full possession and enjoyment of all its rights, by making the safety and independence of every state objects of interest and guardianship to all its neighbours. It endeavours to accomplish this great end by teaching, that it is the interest of all states to check the first encroachments of ambition; to watch every movement of foreign powers; and to unite their respective forces in support of the weak against the strong. It is called the *balancing* system, because its aim is to *prevent* any state from aggrandizing itself to the danger of its neighbours, and to *counterpoise* any state that may in any way have become powerful, by a union of the forces of other states.

The metaphorical terms applied to this system seem to have given rise to some very absurd misconceptions of its true theory and purposes. It has sometimes been supposed, that its object was to *equalize* the powers of states composing a common system; and as it is plainly impossible either to effect, or to maintain such an equality, it has thence been concluded, that the whole system is founded upon a chimera. But, with a view to the objects of this system, the question is, not what amount of power above another any state possesses, provided the power so possessed is fairly acquired,—but whether any state possesses its power in such circumstances as to enable it to trespass at its pleasure on a weaker neighbour. If there is no other state, or confederacy of states, capable of counteracting any injurious designs which its greater power might induce it to undertake, then it is said that there is no balance; but if there is such a counterpoise, this is all that the balancing system requires, and not an equalization of forces, to produce what, in its language, is called an equilibrium. In order to obviate such misconceptions, and to make this point as clear as possible, we beg to refer to the following definitions of the balance of power, as given by Vattel and by Gentz: "By this balance," says the former, "is to be understood such a disposition of things, as that no one potentate or state shall be able absolutely to predominate and prescribe laws to the others." (*Law of Nations*, B. iii. c. 3. § 47.)—"What is usually termed a balance of power," says M. Gentz, "is that constitution subsisting among neighbouring states, more or less connected with one another, by virtue of which, no one among them can injure the independence or essential rights of another, without meeting with effectual resistance on some side, and, consequently, exposing itself to danger." (*Fragments on the Political Balance*, c. 1.)

Thus, then, it is distinctly to be understood, that the balancing system is not grounded upon an *equality* among states in respect of power, but upon a union of powers to repress the enterprises of the strong and ambitious, and to counteract the effects of necessary individual inequalities by aggregate strength.

It is quite indispensable to the existence of such a system, that no one state should be permitted to obtain such a superiority of power as to enable it to overawe all opposition, and make the safety of those around it dependant on its will; and as it is the disposition of all unchecked power to extend itself, the balancing system inculcates it to be the *interest*, as it is the *right*, of every state to join in opposing the first encroachments of any ambitious potentate or community. It teaches, that the danger extends much farther than to the party immediately attacked or menaced; that one encroachment will but pave the way to another; and that it is therefore wise to meet the danger whilst yet distant, and capable of being combated with less peril or loss. The right of interference to put down a danger of this kind is, in fact, only a modification of the right to resist an immediate attack. All human experience shows, that the state which is suffered to aggrandize itself at the expence of one neighbour, will only, with its increased means, acquire stronger dispositions still farther to encroach; and, therefore, self-defence authorizes us to treat that potentate as alrea-

dy an invader, whose conduct entitles us to conclude, that he only waits a convenient opportunity to become so in effect. It is peculiarly and emphatically the language of the balancing system,—*Obsta principiis*,—in other words, look well to the safety and independence of your neighbours, even the most remote, if you wish to preserve your own.

Upon this point it is by no means necessary to enter into any lengthened deductions. The principle of interference to prevent the progress of a dangerous power rests, both as to *right* and *policy*, upon the most obvious dictates of experience and prudence. No state ever yet acquired a preponderating power without abusing it; and, therefore, it is the right and interest of all states to prevent any one from rising to such an ascendancy as may endanger the common safety.

The right in question, however, is that of guarding against an injury justly to be apprehended from the conduct of a state, which uses improper means of aggrandizement. So far, therefore, as measures of hostility are concerned, there must be actual encroachment somewhere in order to warrant them. The balancing system does not say there shall be no alterations in the relative strength of states; for a state may fairly and honourably increase her power by wise legislation, or by the cultivation of her own internal resources. To attempt to impede a state which travels in this road to greatness, would be to make war upon those very arts by whose successful cultivation peace and happiness are spread through the world. The aggrandizements against which the balancing system declares war, are those which do immediate violence to some, and which infer farther violence to others. All that nations can do, when a neighbour becomes formidable in a fair way, is to watch her, and to draw closer those ties of alliance which may enable them to counteract any bad use of her power. When Lord Bacon, in his *Essay on Empire*, counsels princes "to keep due centinel, that none of their neighbours do so overgrow by increase of territory, by *embracing of trade*, by approaches, or the like, as to become more able to annoy them than they were;" he could not mean that the growth of a state by commerce was to be prevented in the same way as in the case of its extension by a seizure of territory; but that all great power, however acquired, is in its nature dangerous, and ought to be counterpoised by timely confederation.

There is another way in which a state may become formidable, and that of a sudden, where the balancing system does not authorize immediate hostile interference. We here allude to the case of a sovereign who acquires a great accession of power by marriage or by inheritance. "It is a sacred principle of the law of nations," says Vattel, who discusses this question in reference to the balancing system, "that such an increase of power cannot, *alone and of itself*, give any one a right to take up arms in order to oppose it." (B. iii. c. 3. § 43.) Grotius and Puffendorf maintain the same opinion in terms equally decided. But suppose a sovereign, who has already displayed an encroaching disposition, is about to acquire in this way an accession of power, which would render him more and more formidable to his neighbours; in this case, as Vattel shows, the maxims of the balancing system authorize an immediate interference to procure securities, or, according as the danger is imminent, altogether to prevent his aggrandizement. It is perhaps wholly unprecedented, as this writer observes, that a state should receive any remarkable accession of power, without giving other states just grounds to interfere; but if it should be otherwise, the only course to be pursued is that which the balancing system always recommends—the keeping a watchful eye on all the proceedings of the formidable state, and the formation of a counterpoise to her power by means of alliances.

These are, indeed, the grand expedients of the balancing system—vigilant inspection to discover, and prompt union to counteract, in their birth, all such projects of encroachment, as powerful states, without any external limitation of their power, will ever, when opportunity offers, be ready to form. By employing resident agents to procure speedy information, and the weight of joint warnings and reclamations in every case of apprehended, or of real injury, the balancing system offers the only means which human wisdom can devise to control the conduct of independent states; and the only means which can be employed to guard against injustice, or obtain redress, without an actual appeal to the sword. It was the *habitual* employment of these expedients, with a view to guard against distant dangers, that distinguished the balancing system, as exemplified in modern Europe, from those momentary efforts and loose confederacies in which all nations, and even the rudest tribes, have occasionally united, in order to repel or pull down a powerful and common enemy.* Without this habitual attention to foreign affairs, and constant application of the principles of counterpoise, there cannot, indeed, be said to exist any thing like a system of reciprocal guarantee of the independence of nations, such as is involved in the idea of a balance of power.

What particular alliances each state ought to form, with a view to maintain this balance, is a matter of circumstances, and must vary with them. The object of the system is always the same, to preserve such a distribution of power amidst the varying relations of states, as shall most effectually check the spirit of encroachment, and confine every potentate to his own dominions.

---

* "The grand and distinguishing feature of the balancing system is the perpetual attention to foreign affairs which it inculcates; the constant watchfulness over every nation which it prescribes; the subjection in which it places all national passions and antipathies to the fine and delicate view of remote expediency; the unceasing care, which it dictates, of nations most remotely situated, and apparently unconnected with ourselves; the general union which it has effected of all the European powers, obeying certain laws, and actuated in general by a common principle; in fine, the right of mutual inspection, universally recognised among civilized states in the rights of public envoys and residents." Brougham's *Colonial Policy*, B. iii. § 1.

Balance of Power.

In the preceding observations, we have had it in view to give a general idea of the nature, intention, and means of maintaining a balance of power among a number of connected nations of different degrees of power and magnitude. Before proceeding to any remarks on the history and results of this branch of policy, we shall recapitulate, in the words of M. Gentz, those fundamental maxims which constitute the necessary conditions of the beneficial existence of such a system as we have described. These are,

"That no one state in the common system must ever become so powerful as to be able to coerce all the rest put together;—

"That, if the system is not merely to exist, but to be maintained, without constant perils and violent concussions, every member which infringes it must be in a condition to be coerced, not only by the collective strength of the other members, but by any majority of them, if not by one individual;—and,

"That if ever a state attempts, by unlawful enterprise, to attain, or does in fact attain, to a degree of power, which enables it to defy the danger of a union of several of its neighbours, or even of the whole, such a state should be used as a common enemy; and if it has acquired that degree of force by an accidental concurrence of circumstances, without any acts of violence, whenever it appears upon the public theatre, no means which political wisdom can devise for the purpose of diminishing its power, should be neglected or left untried." (*Fragments upon the Political Balance*, c. 1.)

Ancient knowledge of the Balance of Power, and rise of the Modern System.

II. The knowledge of the ancients in regard to these great principles of national safety, and the period when they came to obtain a decided influence among the moderns, are points of considerable historical interest. Mr Hume has shown, in a very satisfactory manner, that the principle of preserving a balance of power, is distinctly to be recognised in many of the great political transactions of the ancient nations. The anxiety of the Greeks, with regard to it, was particularly manifested in that famous league against the rising power of Athens which produced the Peloponnesian war. Athens herself showed, that she both knew and practised this policy, by constantly throwing her power into the lighter scale, when Thebes and Sparta came to contend for the mastery of Greece. Mr Hume also traces the influence of this salutary principle in the contests which arose among the successors of Alexander; their attention to it having "preserved distinct, for several ages, the partitions made after the death of that conqueror." (*Essays*, Vol. I.) The orations of Demosthenes frequently display very clear and extensive views in this branch of policy. In that for the Megalopolitans, in particular, "we may see," according to Mr Hume, "the utmost refinements on the balance of power that ever entered into the head of a Venetian or English speculatist;" and by a later writer, this speech is also pointed out as "containing discussions of some of the most delicate parts of the theory." (Brougham's *Colonial Policy*, B. iii. § 1.) All who peruse this remarkable oration with due attention, must indeed perceive that it fully bears out this character. Its reasonings may be analyzed into these leading doctrines of the balancing system,—that it is the interest of every state to prevent the formation of a predominating power; that to this end the first encroachments ought to be promptly checked; and that it is necessary to join even a rival against a former friend, when that friend would otherwise infringe upon the balance.*

It seems, in short, to be no longer a question, that it was only with the *phrase*, and not the *idea*, of a balance of power, that the ancients were unacquainted. But we cannot agree with Mr Hume when he goes so far as to say, that this principle, though it has been more generally known and acknowledged in modern times, has not had an authority much more extensive in practice, than in the ancient world. (*Essays*, Vol. I.) This opinion stands clearly refuted by all the great facts, and by the whole tenor of modern history, from the commencement of the sixteenth century. It was the more constant operation of that principle which gradually formed the nations of Europe into one great republic or federal league, whose common bond of union was the guarantee which it afforded of their respective independence. But neither, on the other hand, can we agree with Mr Brougham, when he affirms that the ancient states displayed nothing beyond a mere speculative knowledge in this department. (*Colonial Policy*, B. iii. § 1.) † It may be very true, that those more enlarged ideas of foreign policy, which Demosthenes disclosed in some of his orations, were not generally understood or acted upon by his contemporaries; but it is nevertheless perfectly clear, from Mr Hume's statements, the accuracy of which has never been called in question, that among the Grecian states, the maxim of preserving a balance of power, though it had not produced any course of policy so regular and authoritative as the modern international system, was yet, on many occasions, the sole moving spring of their wars and alliances.

This maxim, indeed, lies so much within the sphere of common sense, that it can scarcely fail to be attended to, wherever there is a collection of states capable of observing and attacking each other. But circumstances may be more or less favourable to the growth of a consistent policy in this respect. In mo-

---

* There is a passage of Polybius, which has been frequently quoted, as pointing out the leading aim of the balancing system in terms the most explicit. The historian, after mentioning that Hiero, king of Syracuse, acted wisely in assisting the Carthaginians in the war of the auxiliaries, adds,—"*Nunquam enim ejusmodi principia contemnere oportet, neque tanta cuiquam astruenda est potentia, ut cum eo postea de tuo quamvis manifesto jure disceptare ex æquo non queas.*" Lib. I. cap. 83.

† It is with considerable diffidence that we venture to question any of Mr Brougham's statements upon this subject. His chapter on the *balancing system*, in the work referred to in the text, is marked by his usual extent of view and of information, and certainly constitutes a valuable portion of that very able and instructive performance.

dern Europe, a number of considerable states were formed under such circumstances as tended peculiarly to promote a regular intercourse among them, and, consequently, to develope and systematize this great principle of national security. But it did not begin to manifest itself until, in the gradual and similar progress of European society, the power of the sovereigns of these states was so far consolidated as to enable them to give part of their attention to foreign affairs, and to send and maintain armies beyond their own frontiers. It was in Italy, where civilization was more advanced, and where there was a number of small states and commonwealths, whose safety required that their rulers should reciprocally keep watch on each other, that the modern system of interference took its beginnings. From an early period of the fifteenth century, we see the balance of power as constant an object of concern among these states, as, in the next, it came to be throughout Europe. "Their jealousy of each other," says Guiccardini, "made them watchful of every motion or measure that they conceived might any way increase the power of their neighbours;" and he draws a splendid picture of the beneficial effects, the long peace, and general independence attendant upon this habitual attention to the principle in question. (*History of Italy*, B. i.)

It was about the end of this century that these ideas began to extend to other quarters, and to actuate the movements of greater potentates. There were now several princes possessed of large consolidated kingdoms, with powers and prerogatives which enabled them to take part in distant wars and negotiations. The first great movement of an ambitious neighbour, would naturally therefore excite their jealousy, and bring them into concert. Thus, when Charles the Eighth of France, in 1494, invaded Italy, and laid claim to Naples, the sovereigns of Germany and Spain saw the expediency of listening to the Italian Princes, who suggested a confederacy to prevent France from gaining an accession of power, which could not but render her a dangerous neighbour. Dr Robertson regards the expedition of Charles as the first great exertion of those new powers, with which the progress of society had invested the princes of Europe; and the confederacy formed against him, as the first considerable extension of those ideas of a balance of power, whose influence had hitherto been limited to the narrow sphere of Italian politics. "From this era," he says, "we can trace the progress of that intercourse between nations, which has linked the powers of Europe so closely together, and can discern the operations of that provident policy, which, during peace, guards against remote and contingent dangers, and in war has prevented rapid and destructive conquests." (*View of the Progress of Society in Europe*, sect. 2.) If we look only a little way beyond this era, we shall everywhere see a constant jealousy of the increase of power, and a vigilant attention to all foreign operations, combined with the application of those means of safety which peculiarly belong to the balancing system. "During that triumvirate of kings," says Lord Bacon, in his usual expressive language, "Henry the Eighth of England, Francis the First of France, and Charles the Fifth, Emperor, there was such a watch kept, that none of the three could win a palm of ground, but the other two would straightways balance it, either by confederation, or, if need were, by a war; and would not, in any wise, take up peace at interest." (*Essays*—on Empire.)

It has been objected to Dr Robertson, much to our surprise, we will confess, considering the very intelligent quarter from which the objection comes, that he has represented "the principle of the balance of power as a *discovery* made by the Italian politicians in *consequence* of this invasion of Charles; whereas, it was not to any such single event that the balancing system owed either its origin or refinement; but to the progress of society, which placed the whole states of Europe in the same relative situation in which the states of Italy were at that period, and taught them not to wait for an actual invasion, but to see a Charles at all times in every prince or commonwealth that should manifest the least desire of change." (Brougham's *Colonial Policy*, B. III. § 1.) What is here said as to the origin of the balancing system is no doubt true. We have already stated, that the principle on which it rests, is a principle of our common nature, which cannot fail to manifest itself in certain situations; but that nations must have arrived at an advanced stage of civilization and intercourse, before it can be acted upon with consistency and concert. It would, therefore, be absurd to represent that system as taking its rise in any single event, or its principle as a discovery of some long-sighted statesman. But Dr Robertson knew human nature too well to seek the origin of this principle in an accidental occurrence; and he knew history too well to fix its origin "as a consequence" of Charles's invasion. On the contrary, throughout the whole of his masterly chapter on the progress of the nations of Europe, with respect to the command of the national force requisite in foreign operations, he speaks of this system as holding progress with the growing improvement and intercourse of these nations; and so far from representing the principle of the balance of power as a discovery *consequent* upon the event alluded to, he expressly speaks of the league against the French monarch, as only exemplifying an *extension* of those ideas which had long been familiar to the Italian statesmen, "in regulating the operations of the petty states in their own country." (*View of the Progress of Society*, sect. 2.)

Before concluding these very general remarks on the rise of the balancing system in modern times, we shall briefly advert to a conjecture of M. Villers upon this subject, which occurs in his able work on the Reformation. Long before the states of Europe became united in a general system, Italy and Germany, he observes, had formed partial systems, with a view to restrain the members within them, each by the other, and thus maintain a balance of power. It is possible, he adds, that the idea of the *general* balance of Europe may have been copied from these partial confederacies. (*Essai sur l'Esprit et l'Influence de la Reformation, 2de Partie.*) This conjecture, if we rightly understand the learned author, appears to us exceedingly unphilosophical. The states of Europe embraced the idea of a balance of power in proportion as their circumstances enabled them to act upon it;

Balance of Power.

and not in consequence of any estimate of its effects, as displayed on those earlier and narrower stages of its agency.

General Results, and recent History of this System.

III. It appears, then, to have been about the beginning of the sixteenth century that the principle of maintaining a balance of power came to be generally recognised and acted upon by the states of Europe; "at first," as M. Gentz says, "more in a practical way, and, as it were, from political instinct, but afterwards with clear, reflecting, and methodical constancy." (*Fragments.*) What were the advantages which Europe reaped from this course of policy, we shall endeavour to show, after we have adverted to certain arguments generally employed by those who wish to give an unfavourable view of the balancing system.

By some, this system is represented as productive only of sanguinary wars, as but a convenient pretext to cover projects of ambition, or to screen the restless movements of national jealousy. Others talk of it as being merely a brilliant conception; and appeal to the many violences and usurpations which modern history records, as proofs, if not of its nonentity, at least of its inefficacy. But there is surely but little respect due to that sort of estimate of the system, which is founded solely on the abuses to which it is liable, or upon imperfections from which no human institution can be made free. They who decry, or who ridicule the balancing system, should be prepared to show,—not that it has sometimes afforded plausible pretexts for unnecessary wars, or has sometimes failed to protect the weak against the outrages of the strong,—but that it is wholly useless to interest ourselves in the safety of neighbouring nations; to take any trouble to avert dangers which are yet distant; or to seek to strengthen ourselves against a powerful enemy, with any strength not our own. This view of things, were it to prevail, would, as M. Gentz observes, open the most desirable prospects to every sovereign whose power and ambition might prompt him to aspire to universal domination.

It must, we think, appear abundantly obvious to every one who reflects calmly upon the subject, that the balancing system is, upon the whole, greatly favourable to peace. The wars which peculiarly belong to it, are in the nature of a sacrifice of a smaller present, to secure a greater future good; and the tendency of the system is to render these wars less and less frequent. The evil passions which give rise to ambitious attacks, like all other evil passions, will be more apt to be indulged, the less exposed they are to opposition or restraint. And it cannot be questioned, that in proportion as the maxims of this system are vigilantly and steadily pursued, there will be less inducement, because less prospect of success to ambitious undertakings.

Its object is to alarm, and to arm all against the prince whose power prompts him to transgress upon others; and the prince who knows that all his motions are keenly watched, and that his first successes would only expose him to a more extended contest, must see how hopeless would be any attempt to possess himself of the territories even of the weakest of his neighbours. Such is the general tendency of the system; and however it may have occasionally failed to prevent outrages, it cannot be doubted, that it has proved a formidable barrier against conquest, and a rampart of defence to the weaker states.

The complaint of a certain class of French politicians, alluded to by Mr Burke, in his *Letters on a Regicide Peace*, "that Rome had frequently acquired more territory in a *single year*, than all the power of France, actuated by all her ambition, had enabled her to acquire *in two centuries*," forms, in fact, though unintended, one of the finest panegyrics that could have been pronounced upon the salutary influence of the modern system. The advocates of that system can, indeed, appeal to history for the most satisfactory of all proofs of its efficacy, in the remarkable fact, that, for a period of nearly three centuries, no European state, however small, lost its independence from external violence. When we recollect the number of small states which, during so long a period, enjoyed an independent existence on the immediate frontiers of powerful nations; and reflect for a moment on those evil passions which have, in all ages, prompted the strong to prey on the weak; we must admit that, but for that salutary jealousy of power, and united resistance to its encroachments, which it was the object and office of this system to nourish and enforce, these otherwise helpless states would have been speedily absorbed, or their independence annihilated, by the mighty masses with which they were in contact. It was not the preservation of such countries as Portugal or Holland, of Sweden or Denmark, which, though small compared with many others in the system, were yet possessed of considerable means of self-defence;—it was not the preservation of such states as these merely, but of a multitude of feeble, though happy communities, in Germany, in Switzerland, and Italy, which affords the proudest proof of the salutary influence of the balancing system on the fortunes of modern Europe. "Consider, for instance," to use the impressive words of a distinguished writer and orator, "the situation of the republic of Geneva; think of her defenceless position in the very jaws of France; but think also of her undisturbed security, of her profound quiet, of the brilliant success with which she applied to industry and literature, while Lewis the Fourteenth was pouring his myriads into Italy before her gates; call to mind that happy period, when we scarcely dreamt more of the subjugation of the feeblest republic of Europe, than of the conquest of her mightiest empire; and say, whether any spectacle can be imagined more beautiful to the moral eye, or which affords a more striking proof of progress in the noblest principles of true civilization." (Mackintosh's *Speech on the Trial of John Peltier*, in 1803.) *

* Our readers will thank us, we think, for adding the following extract, in reference to our subject, from this justly celebrated oration. "These small states were, in many respects, one of the most interesting

Such were the great and noble results of the system founded on the balance of power. It was a bridle upon the strong, and a bulwark to the weak. When it failed to prevent the inroads of violence and injustice, it yet acted as a restorative principle, and replaced injured nations in their former state of independence. It was at the memorable and fatal era of the partition of Poland in 1772 that it first lost this character,—that the first example was set of a deliberate, successful, unchecked conspiracy, against the independent existence of an unoffending country. It is here proper to mention, that some authors have spoken of this infamous transaction in terms which seem to imply, that it was quite in consonance with the principles of the balancing system.* It is indeed true, that the maxims of that system were still so far operative as to effect a relative equality in the division of the spoil. But, as the whole intention of this system is to maintain the integrity and independence of nations against unlawful attacks, the partition was just as diametrically opposite to its principle, as if the whole spoil had been appropriated by one robber, instead of being shared by three. The equality of the division did not take away from the danger of the example; the example of states combining, not to uphold but to destroy,—not to enforce respect to the great principles of national safety, but to set them at defiance; an example too soon followed by similar violences, and which, in fact, paved the way to that total overthrow of the ancient system of Europe which ere long took place.

The *origin* of a project so pernicious in its consequences is a matter of some interest in the history of the balancing system. We learn, for the first time, from Rulhiere's *Histoire de l'anarchie de Pologne*, published in 1807, that the distractions of this country had suggested the project of a partition so early as 1658; that a Swedish minister, named Stippenbach, proposed it to his own court, to Austria, and the Grand Duke of Prussia, whose armies were then in possession of the country; and that it would, in all probability, have been acted upon, but for the discovery of the scheme by France, and consequent interference of that power.† With regard to the project actually carried into execution in 1772, each party concerned was desirous to shift the blame of the first proposal to the others; but it was generally believed to have originated with Frederick, though some were of opinion, that he was indebted for the idea to his brother, Prince Henry. Frederick, however, in one of his posthumous pieces, *Mémoires de 1763 jusqu'à 1775*, states, that the scheme was devised by the Empress Catharine; and this is corroborated by M. Rulhiere, who asserts that she communicated it to Prince Henry, during his visit to St Petersburgh in 1770; a piece of information, he adds, which was detailed to him, in the most circumstantial manner, by three different secretaries, who accompanied the Prince to the Russian Court. (Tom. IV. p. 151, 210.) It seems to be generally acknowledged, that the proposal, when first made to the cabinet of Vienna, was opposed by that power; and that her accession would not have been obtained, but for the astonishing apathy displayed by France, and, indeed, by all the other states of Europe. The silence of England during the perpetration of this shameless plot against the independence of nations, if it can be accounted for, can never, at any rate, be excused; inasmuch as the fact appears pretty well established, that, had she, as the guardian of the political balance,

---

parts of the ancient system of Europe. Unfortunately for the repose of mankind, great states are compelled, by regard to their own safety, to consider the military spirit and martial habits of their people as one of the main objects of their policy. Frequent hostilities seem almost the necessary condition of their greatness; and, without being great, they cannot long remain safe. Smaller states, exempted from this cruel necessity—a hard condition of greatness, a bitter satire on human nature—devoted themselves to the arts of peace, to the cultivation of literature, and the improvement of reason. They became places of refuge for free and fearless discussion; they were the impartial spectators and judges of the various contests of ambition, which, from time to time, disturbed the quiet of the world. They thus became peculiarly qualified to be the organs of that public opinion which converted Europe into a great republic, with laws which mitigated, though they could not extinguish, ambition; and with moral tribunals to which even the most despotic sovereigns were amenable. If wars of aggrandizement were undertaken, their authors were arraigned in the face of Europe. If acts of internal tyranny were perpetrated, they resounded from a thousand presses throughout all civilized countries. Princes, on whose will there were no legal checks, thus found a moral restraint which the most powerful of them could not brave with absolute impunity. They acted before a vast audience, to whose applause or condemnation they could not be utterly indifferent. The very constitution of human nature, the unalterable laws of the mind of man, against which all rebellion is fruitless, subjected the proudest tyrants to this control. No elevation of power,—no depravity, however consummate,—no innocence, however spotless,—can render man wholly independent of the praise or blame of his fellow-men."

* See, for example, the terms in which Count Hertzberg speaks of the partition in his essay *Sur la Balance du Commerce et celle du Pouvoir*. (*Oeuvres*, Tom. I.) The language of M. Gentz upon this subject, in his able work, *L'Etat de l'Europe avant et auprès la Revolution Françoise*, is extremely exceptionable; but, in his later work, so often referred to in this article, he condemns the partition as wholly inconsistent with every sound idea of a balance of power, and as having in fact led to the subversion of the balancing system.

† *J'ai retrouve*, says M. Rulhiere, *dans les archives des affaires étrangeres de France, cette anecdote importante, et jusqu'à présent ignorée*. Tom. I. p. 9.

raised her voice against the partition, Europe might have been saved from the fatal effects of that new system of robbery and oppression, which the spoilers of Poland were suffered, without any sort of interruption, to exemplify. "To my certain knowledge," says Mr Burke, "if Great Britain had at that time been willing to concur in preventing the execution of a project so dangerous in the example, even exhausted as France then was by the preceding war, and under a lazy and unenterprising prince, she would have at every risk taken an active part in this business." (*Thoughts on French Affairs in* 1791.)

It would lead us much beyond our limits to detail that long series of violences, and transfers of dominion, too faithfully copied from the example of the first and succeeding partitions of Poland, by which all remains of the ancient system were for a season swept from the earth. * We more gladly proceed to observe, that the time has again arrived when the nations of Europe may and ought to unite, not, indeed, to rebuild the ancient edifice in its former proportions, that being rendered impossible from the many melancholy changes which have taken place; but carefully to recal, and steadily to adhere to those great principles which constituted its foundation, and to which it owed all its beauty and strength. It is not enough to have overthrown a power which domineered over all, and to have reinstated some other powers in their pristine strength and influence. The foundations of the ancient structure were first sapped by a shameless disregard of the sacred principles of public justice; and if the balance of power, in the full and sound acceptation of the term, is again to become an object of the foreign policy of nations, those guardian principles must hereafter constitute the rules of their conduct, in all the public transactions of Europe. Let us here again quote the words of M. Gentz, written in 1806, in a too early hope of the approaching deliverance of the Continent. He is speaking of the transition which in that event ought to follow "to a state of things founded upon a balance of power." In order to this, says he, "every just and conscientious government must set it down as an unchangeable maxim, never henceforth to lend an ear to plans which are not founded in the strictest equity. In the next place, though, in the proper sense of the term, a general code of laws cannot be framed for the regulation of a confederacy of states, at least no means should be left untried, to procure for this maxim a common sanction, and the solemn ratification of treaties. In every considerable alliance, in every treaty of peace, *particularly in every congress composed of several considerable powers*, the parties must mutually engage themselves not to extend their territory by unjust means; and not to enter into any scheme or association directed against the rights or possessions of an independent state, by whatever name it may be

---

* The following passage, though rather declamatory, contains some striking ideas as to the way in which the infamous partitions of Poland contributed to this general overthrow. "What rendered the project of a partition of Poland so incomparably more destructive to the higher interests of Europe than any former acts of violence of apparently a more aggravated character, was the decisive circumstance of its originating in that very sphere from which was expected to flow nothing but benefits and blessings, security in time of peace, and salvation in periods of danger. An union between several regents had been always considered as a beneficial barrier against lawless power, and the passions of an individual oppressor; it now appeared, to the terror of the world! that such an union could be formed for the purpose of bringing about precisely that evil against which it seemed destined as a bulwark of defence. The impression made by this detestable discovery must be still deeper and more painful, when we reflect that the framers of the wicked project, in the whole course of their undertaking, adopted the principle of the political balance as a star to conduct them through it; that they acted conformably to this principle as far as circumstances would admit, in the adjustment of their respective interests, and that while they inflicted upon its spirit the most frightful wounds, they borrowed its attire, its forms, and even its language. Corruptio optimi pessima. To witness such an abuse of the noblest mean which the European commonwealth possessed for assuring its safety and welfare, was, in itself, a revolting spectacle; but the malignant character of the deed was first completely brought to light in its consequences. The cause of public justice was on all hands abandoned and betrayed. A horde of jabbering sophists, who, at that time in France, were striving to shake the foundations of all principle, and to undermine every existing constitution, now that the mighty of the earth had broken into the sanctuary of national right, not under the impulse of incendiary passions, but deliberately and systematically, turned the most respectable political ideas into ridicule, without fear or reserve. Even among the enlightened and upright of the time, only a few escaped the dreadful contagion. Notwithstanding that what is purest in its nature may be profaned, and what is most wholesome may be poisoned—notwithstanding that the fatal blow which the federal constitution of Europe had received, called upon them the more loudly to unite, to establish the foundations of the building on a firmer basis, and more vigorously to exert themselves in its defence, they either gave themselves up to a comfortless incredulity in the efficacy of political maxims, or to a systematic indifference. The multitude, misled by the former, or not sufficiently warned against the latter, sunk every day deeper in the bottomless void, and became more and more accustomed to expect their law from violence, and their salvation from chance. How much this fatal habit of thinking must have contributed to facilitate crime, and spread desolation, when at last the evil days arrived when all right was trampled under foot, the ruin of all order conspired, and the whole social machine disjointed and broken, can have escaped only the inconsiderate observer."—Gentz's *Fragments upon the Political Balance of Europe*, p. 76.

Balance of Power.

called, *whether of dividing, of rounding, of concentrating, of uniting, or of indemnifying themselves for other losses.* A sort of *anathema* must also be pronounced by anticipation against all such as shall project such violations of right, or call upon others to assist them; so that a lively conviction may be again established in the public mind, that when princes and states enter into combinations with one another, their objects are protection and defence against common danger, never the attack and invasion of the innocent." (*Fragments*, cap. 3.) Whether these precepts of this great enemy of the late ambitious ruler of France, and advocate of those by whom he was overthrown, were taken as the guides of that "Congress of Powers," which lately met for the purposes of general pacification, we shall leave to others to determine; but thus much our present subject requires us to state, that, without a return in good earnest to those sound and salutary maxims, no durable peace is to be hoped for Europe, and no restoration of that system of balance by which Europe was so long distinguished and protected.

Interest of Great Britain in the Balancing System.

IV. We have still to allude, and we can here but barely allude, to the great question, whether Britain, protected as she is on all sides by nature, ought to consider it as a necessary part of her policy to attend to the European balance of power? This has been considered as constituting a separate question, by some who make no doubt that the other states of Europe could not long preserve their independence secure through any other course. Taking the question generally, we do not think there is any great difficulty in regard to it. With the multitude, to be sure, it always will be popular to argue, that Britain stands in need of no other defence than what the seas and her invincible navy afford her, and that all continental connexions are useless or pernicious. But the argument from the advantages of our insular situation would not in fact bear out this conclusion, even were the seas and the navy a stronger defence than it is possible they always can be. Our commerce and our colonies, the supports of that navy, render it indispensably necessary that we should more particularly observe some nations, and ally ourselves with others. These great concerns make it, indeed, nothing less than absurd to talk of our being *insulated* as an empire or state because Britain is an island. And, with regard to invasion, it is clear, that we could not always be as secure, and as free from uneasy apprehensions, in a state of total insulation from foreign connexions, as with friends and confederates to employ or oppose a formidable enemy on his own confines.

But supposing the balance of power to constitute a great national object, the line of conduct which that object imposes upon us may, no doubt, be affected by our insular situation. We may on some occasions allow other nations who are more exposed to danger, and who ought, on that account, to be more on the alert to prevent encroachments, to take the first measures, and bear the first expence of resistance. We may watch and warn, and use the influence of our remonstrances and our counsels, without having recourse, except in urgent cases, to the extremity of arms. It is only, in a word, as to the *application* of the general principle, and not as to its being necessary and worthy to be entertained, that there seems any fair room for difference of opinion among British statesmen. In point of fact, all our later statesmen, however differing in other respects, have distinctly assented to the *general* doctrine, that the maintaining a balance of power was an interest of the highest importance to England. The last time, we believe, that this general question can be said to have been fairly brought into debate, and fully discussed in Parliament, was on occasion of the famous armament against Russia for refusing to restore Ocazakow to the Porte; and on that occasion, though Mr Fox and his followers reprobated the armament in the strongest terms, they did so, not because they denied the great principle to which the minister appealed, as the sole justification of the measure, that the balance of power was a British concern, and gave Britain an undoubted interest to interfere in the affairs of the Continent,—not because they thought that Britain ought never to guard against any distant danger,—but because there was no such degree of danger from the retention of that city and its district, as called upon this country to interfere at the risk of a war. *

If there be any certain medium between the policy which Britain and other countries ought to observe with a view to the balance of power, we do not know that it can be pointed out in more specific terms than in the following passage of one of Lord Bolingbroke's political pieces, with which we shall conclude this article. "Other nations must watch over every motion of their neighbours; penetrate, if they can, every design; foresee every minute event; and take part, by some engagement or other, in almost every conjuncture that arises. But as we cannot be easily nor suddenly attacked, it may be our interest to watch the secret workings of the several councils abroad; to advise and warn; to abet and oppose; but it never can be our true interest *easily* and *officiously* to enter into action, much less into engagements that imply action and expence." (*Idea of a Patriot King.*)

---

* Earl Grey, the only survivor of that illustrious group of orators and statesmen who opposed the armament, repeatedly and forcibly declared his adherence to the general doctrine; affirming, that though the epithets, wild and romantic, had sometimes been applied to it, he nevertheless considered the poorest peasant in England as interested in the preservation of the balance of power; and that this country ought to interfere whenever that balance appeared to be really in danger. Of all those who joined in this opposition, Mr Burke was the only statesman who did so upon a ground, as it appears to us, equally erroneous in *fact* and *principle*, namely, that Turkey never had, nor ought to be taken into consideration, in any question as to the maintenance of the balance of power in Europe.—See *Debates in the House of Commons*, 29th March, and 12th April 1791, and 29th February, and 1st March 1792.

Baldinger || Balm of Gilead.

BALDINGER (Ernest Godfrey), a German physician of considerable eminence, and the author of a great number of medical publications. He was born near Erfurth, May 13, 1738, and was originally destined for the church; but having acquired a strong predilection for medicine, his father yielded to his wishes, and allowed him to embrace that profession, and he prosecuted his studies with this view both at Erfurth and at Jena. In 1761, he was entrusted with the superintendence of the military hospitals connected with the Prussian encampment near Torgau; and he there gave public lectures with great applause. Having acquired considerable experience in army practice, by his assiduous attention to the duties of his office, he published, in 1762, a dissertation on the diseases of soldiers, which met with so favourable a reception from the public, that he enlarged the plan of his work, and republished it under the title of *Treatise on the Diseases that prevail in Armies,* Langensalz, 8vo, 1774. It has since gone through another edition. In 1763, he was appointed professor of medicine at Gottingen, where he enjoyed considerable reputation. The Landgrave of Hesse Cassel, Frederic II. invited him to take up his abode at Cassel, conferring upon him the title of first physician to his court, and director-general of all his medical establishments. He was afterwards professor of the theory of medicine at Jena; and in 1785, was promoted to a professorship at Marpurg, where he died of apoplexy on the 2d of January 1804.

His writings are exceedingly numerous; many of them are scattered in various collections and journals; but besides these, no less than eighty-four distinct treatises are mentioned as having proceeded from his pen. He had collected an extensive library, consisting of 16,000 volumes, of which a catalogue was published after his death. His funeral oration was pronounced by Professor Creutzer. He was well versed in botany, and has published several works on that branch of natural history, of which the principal are the following: *Catalogus Dissertationum quæ medicamentorum historiam, facta, et vires exponunt.* Altemburgi, 1768. 4to. *On the Study of Botany, and the method of learning it,* in German. Jena, 1770. 4to. He was for many years the editor of a periodical work, entitled *Magazine for Physicians,* 12mo, Cleves; and afterwards changed its name to the *New Magazine,* in 8vo, from 1779 to 1799. But the principal work of this kind which he conducted, was his *Sylloge Opusculorum Selectorum Argumenti Medico-Practici,* being a collection of detached essays and dissertations, which extended to 6 vols. 8vo. Gottingen, 1766—1782.

His *Litteratura universæ Materiæ Medicæ,* &c. Marpurg, 1793, 8vo, is a work of great labour, but little discrimination. He edited *Bœrner's Lives of Physicians,* in German. The only other work of his deserving notice, is the *Historia mercurii et mercurialium medica.* Gotting. 2 tom. 8vo. 1783 and 1785. (w.)

BALM OF GILEAD. The earliest specifics against personal injuries resorted to by mankind, were probably the different parts of vegetables produced in their respective countries; and hence we find, that most savages are acquainted with vulneraries prepared by the hand of nature, or that they seek to improve them from decoctions and infusions of roots, flowers, and leaves. Among the more precious substances obtained from plants, applied as a curative of wounds by the ruder inhabitants of the eastern climates, the balm of Gilead, or balsam of Mecca, has been eminently distinguished during many ages. But although the balm of Gilead is better known from several scriptural allusions, and most esteemed, it is only of secondary quality to the balsam of Mecca, for which it is frequently substituted, and illustrations of its nature and properties must chiefly be derived from the latter. This balsam is a resinous matter, exuding, like ordinary resin, from incisions in the bark of two different vegetables, at least there are apparently two, though the distinction is not well characterized or described by naturalists, which has excited conjectures that there is only one, and that it is subject to certain external modifications from soil and climate. The plant producing the balsam of Mecca, was first ascertained by Forskal to belong to the genus *Amyris.* He transmitted one or two specimens to Linnæus, who has characterized it as the "*Amyris Opobalsamum,* leaves pinnate, with sessile leaflets, a native of Arabia;" while he characterizes the other "*Amyris Gileadensis,* leaves ternate, very entire peduncles, one flowered lateral, a native of Abyssinia." But, to consider it more in detail: This plant grows to the height of fourteen feet, flourishing in a hot climate, and in a stony barren soil. In general it is lower, and Mr Bruce describes a specimen five feet and a half in height, and five inches across the stem where thickest. The wood is white, light, and of open texture, covered with a smooth bark, reddish or of bluish white, resembling that of a healthy standard cherry-tree, green within, and emitting a very fragrant odour. That of the branches, which are very flexible and resinous, is equally agreeable. The leaves, which are evergreen and scanty, bear some resemblance to those of rue; and the flowers, which are leguminous, and of a purplish colour, resemble those of the acacia. The fruit consists of small pointed ovoidal berries, containing a yellowish fluid similar to honey, of a bitterish taste, and exhaling a pleasing perfume, approaching the odour of balm. This plant is called *Balessan* in the east; but it would require new botanical researches to ascertain definitely, and beyond dispute, whether it is of different species, as is most probable, and what is its real character,—points which we must consider as remaining to be established.

It has been maintained, that the plants producing the balsam of Mecca are restricted to a plantation, extending little more than 30 acres, at Beder Hunein, a station for pilgrims in Arabia, half way between Mecca and Medina. Yet it cannot be positively affirmed if this be one distinct species; that Abyssinia, the country ascribed to the other, is deprived of it; or that the balm of Gilead grows in Abyssinia exclusively. These are facts which also require elucidation in future botanical research. The

Balm of Gilead.

plantation belongs to a noble family of Arabs, of the tribe Beni K'oreish, from which Mahomet originated, unless the incursions of the Wahabee, who interrupted the wonted pilgrimages, may have dispossessed them.

The balsam flows from incisions in the tree, which are made with an axe, in July, August, and the beginning of September, when the circulation of the sap is in the greatest activity; and it is received into a small earthen bottle. Each day's produce is collected, and poured into one of larger dimensions; but the quantity obtained is very small, and its collection tedious and troublesome; for the total exudation is usually but three or four drops in a day; nor does the most productive tree afford above sixty. Its scarcity, therefore, and the difficulty of procuring it, have no inconsiderable effect in enhancing its value. The odour is at first strong and pungent, occasioning a sensation like that of volatile salts rashly inhaled. Its intensity is proportioned to its freshness and the care it receives, for if neglected, and exposed to the influence of the air, the fragrance entirely decays. It is also of a rough, acrid, pungent taste. Originally the balsam is of a light yellow colour, a little turbid, and of a whitish cast, which is supposed to arise from the globules of air absorbed along with it; and it dissolves readily in water. It next acquires greater consistence, resembling honey, and becomes pellucid; and after the lapse of some years, grows of deeper yellow, or gold colour, when it is very tenacious, and may be drawn out in threads. It is difficult, however, to obtain the balsam in a state of purity, for several different substances are employed in its adulteration; to detect which various experiments are resorted to. If dropped into a glass of clean water, it falls to the bottom without rising again to the surface, or if remaining still on the surface, like oil in a drop, it is certainly adulterated. If, on the contrary, it spreads on the surface of the water, diffusing itself in a thin pellicle, scarcely visible to the eye, and may be collected with a thread or a feather, it is the pure and natural product. In this state it will coagulate in milk, but not if otherwise. If pure it collects in a globule, when dropped on hot iron; if adulterated it runs and spreads itself all around. The different substances used in the adulteration of this balsam are honey, wax, oil of sesamum, turpentine, and ostrich fat. Sweetness of taste betrays the honey, and its turbid appearance the presence of wax. Adulteration with oil is detected by its yielding a darker and grosser flame than what issues from the genuine balsam, when dropped on burning coals. When the consistency becomes too great, which seems a consequence of age and long preservation, fluidity is restored by the simple application of heat.

Besides the balsam now described, which is the purest and most valuable kind, and is called Opobalsamum, other two of inferior quality are obtained from the balessan; first, Carpobalsamum, which is prepared by expression from the fruit when it has attained maturity, and, if good, should be ponderous, of a pungent taste, and balsamic odour. Secondly, Xylobalsamum, which is elaborated from a decoction of the twigs. These are collected in small faggots, and sent to Venice, and the quality determining them to be the shoots of the year, is said to consist in their being knotty, the bark red, the wood white, resinous, and also exhaling balsamic odour. Various impostures are likewise practised here, in substituting spurious compounds for the real drug; and the ingenuity of mankind in this species of deception has been carried to such an extent, that detection proves extremely difficult.

Numerous virtues are ascribed to the balm of Gilead, so numerous, that modern empirics, availing themselves of that credulity which characterizes our nature in such matters, do not hesitate to offer specifics of their own invention, under the same name, with bold asseverations, that the human race will there find a palliative for most of the evils with which they are afflicted. Prosper Alpinus, one of the older naturalists, ascribes many properties to the balsam of Mecca, esteemed the most precious of all that bear the appellation of balsam, and which, in ordinary description, we must consider synonymous with the balm of Gilead; and the modern Arabs, Turks, and Egyptians, entertain great confidence in its efficacy. It is a powerful vulnerary; a quality of which Mahomet took advantage, for he affirmed, that a grove of the trees sprung up from the blood of his own tribe killed in battle, the juice of which cured the wounds of the faithful, however deadly, nay, that it recovered some of them from death itself. Hasselquist says, it is useful as a stomachic in doses of three grains. It is also taken for complaints in the breast, in fevers, and is applied for rheumatism. Its repute as an antiseptic is very great; and it is esteemed so effectual an antidote against the plague, that when this distemper makes its appearance, the Egyptians take a certain quantity daily. The balsam of Mecca, however, is principally used as a cosmetic by the eastern females of rank: after being kept in a very warm bath, the face and breast are anointed with it, and the same process is continued every third day during a month. Oil of almonds, and other cosmetics, are then rubbed over the same parts, whereby the skin and complexion are beautifully renovated. Lady Mary Wortley Montague relates, that she was induced to try the experiment; and that, in consequence, her face became swelled and red for three days, during which time, she suffered so much pain as to restrain her from repeating the application. But her complexion was greatly improved, and she adds, that the ladies of Constantinople, by whom it is used, have the finest bloom imaginable.

The balm of Gilead has been celebrated from very remote antiquity. We have the testimony of Moses, that it was an article of commerce in the earlier periods of Jewish history; for at the time Joseph was confined by his brethren in a pit, and during their deliberations on his fate, it is said, "And they sat down to eat bread; and they lifted up their eyes and looked, and behold a company of Ishmaelites came from *Gilead*, with their camels bearing spicery, and *balm*, and myrrh, going to carry it down to Egypt." Jeremiah particularly alludes to the virtues of the *balm in Gilead*. Josephus, however, does not

Balm of Gilead.

carry the knowledge of it so high, for he observes, the queen of Sheba or Saba, "who was inquisitive into philosophy, and on that and other accounts was also to be admired," brought the balm of Gilead as a present to Solomon, on her visit to Jerusalem, about 1000 years before the Christian era. "They say also, that we possess the root of this balsam, which our country still bears, from that woman's gift." This is not inconsistent with the words of Jeremiah, who probably flourished about 400 years later; and to reconcile those of Moses with this account, some critics have supposed that Judea did not possess the real balm of Gilead earlier than the queen of Sheba's gift, but an inferior kind of balsam,—a fact not improbable. Further, that, what was in highest esteem as the balm of Gilead, was in truth the balsam of Mecca. The best testimony of its value, is its having been the subject of royal donation among other rarities brought for the acceptance of so illustrious a prince as Solomon. It appears from the writings of the ancients, not far from contemporary with Josephus, that Judea was generally believed to be possessed of it exclusively. Pliny remarks, "but to all other odours whatsoever, is to be preferred that balsam which is produced in no other part of the world than the land of Judea, and there in two gardens only, both belonging to the king, one not exceeding twenty acres in size, and the second still smaller." Strabo, however, in the opinion of Mr Bruce, ascertained the real place of the origin of the balsam, in ascribing it to that country over or near to which the queen of Sheba reigned. "Near to this," he says, "is the most favoured land of the Sabeans, and they are a very great people. Frankincense, myrrh, and cinnamon, grow among them, and in the coast that is about Saba, the balsam also." Whence Mr Bruce observes, that "among the myrrh-trees behind Asab, all along the coast to the Straits of Babelmandel, is its native country. It grows to a tree above fourteen feet high spontaneously, and without culture, like the myrrh, the coffee, and frankincense-tree; they are all equally the wood of the country, and occasionally cut down for fuel." Diodorus Siculus likewise affirms that this balsam grew in a valley of Arabia Felix. But Mr Bruce, who has investigated the subject with considerable care, supposes that it was towards the era of Pliny that it received its name of *Balsamum Judaicum*, or balm of Gilead; and thence became an article of commerce and fiscal revenue, which might probably operate as a discouragement to bringing it from Arabia; as also that it might be prohibited as contraband. Some centuries later than the time of those ancient authors, we see that it was known in Arabia, and perhaps in the place now most celebrated for it. A traveller who assumes the name of Ali Bey, in a very recent work, says, that there is no balsam made at Mecca; that, on the contrary, it is very scarce, and is obtained principally in the territory of Medina; as also that it was called *belsan*. As the repute of the balsam of Mecca rose, the balm of Gilead disappeared, though in the era of Galen, who flourished in the second century, and travelled into Syria and Palestine purposely to obtain a knowledge of this substance, it grew in Jericho, and many other parts of the Holy Land. The cause of its total decay has been ascribed, not without reason, to the royal attention being withdrawn from it by the distractions of the country. In more recent times, its naturalization seems to have been attempted in Egypt; for Prosper Alpinus relates, that forty plants were brought from Arabia by a governor of Cairo, to the garden there: ten remained when Belon travelled in Egypt, nearly 250 years ago; but whether from not agreeing with the African soil or otherwise, only one existed in last century, and now there appears to be none.

The balsam of Mecca has always been deemed a substance of the greatest value. When Selim, Emperor of the Turks, reduced Arabia and Egypt under his dominion in the year 1516, he exacted a tribute of three pounds weight of it yearly, which continues to be sent to Constantinople to this day. Besides this, part of the governor of Cairo's appointments include a right to receive a pound of balsam; the like quantity was due to an officer who conducted the caravan of pilgrims to Mecca; and half a pound to the Pacha of Damascus, who superintends the whole pilgrimage.

Notwithstanding the celebrity of this plant, Mr Bruce denies that it had ever been seen by the ancients, by whom he probably means the Romans, as their descriptions are so various and discordant. Prosper Alpinus, who lived in the sixteenth century, does not seem to know the real class to which it belongs, and even within these few years M. Duplessy, who has paid much attention to the exudations of vegetables, is apparently not aware of its having been figured by Bruce, and also more recently by Dr Woodville. Such uncertainties of old excited a violent dispute between the inhabitants of Rome and Venice—whether the drug used in a medicinal compound was truly the balm of Gilead; and the point being referred to the Pope, his Holiness directed that information should be obtained in Egypt, in consequence of which he decided in favour of the Venetians.

The balsam of Mecca is not the only one possessing exclusive medicinal properties, though it is, perhaps, more eminently distinguished by them. Sixteen balsamic plants of the same genus are enumerated by botanists, each exhibiting some peculiarity; and the balsam of Tolu, obtained from the incisions of a shrub growing in some of the South American provinces, is thought to approach the nearest to the virtues of the former. It is highly aromatic, a powerful antiseptic, and not less efficacious as a vulnerary. It is also very rare and difficult to be procured, which has induced impostors to offer adulterations or counterfeits under its name. That which is particularly substituted is the balsam of Peru, the product of another tree, and can be obtained in abundance either from incisions or decoction of the different parts. The secretions of these plants, however, are neither invariably odoriferous nor salutary; the balsam of Carthagena exhales a penetrating disagreeable smell; and there is a low evergreen shrub, a native of North Carolina and the Bahama Islands, producing a fruit which is deadly poison, and a balsam as black as ink. (s.)

Baltic.

BALTIC SEA. The denomination of the Baltic, applied to the inland sea which forms the subject of this article, is first found in the work of Adam of Bremen, who was canon of that city at the close of the eleventh century, entitled *Chorographia Scandinaviæ.* **Name.** The etymology of this name has given rise to many conjectures. The Swedes derive it from the Scandinavian word *Baelt*, a girdle, because its waters encircle the land; the Prussians from the Sclavonian or Lettonian word *Balt*, white, from its being frozen part of the year, or from *Baltus*, one of their kings; and by others it is derived from *Baltea*, the name of an island mentioned by Pytheas, a merchant of Marseilles, who, in the second or third century before the Christian era, is supposed to have sailed as far north as this sea. In the countries which bound it, its ancient name was *Variatzkoiè Morè*, or the Sea of Variaghi; by the modern Russians it is called *Baltiskoè Morè*; and by the Swedes, Danes, and Germans, the *East Sea.*

General Description. I. The Baltic is entered from the British or Northern Ocean by the Scagerac, Cattegat, Sound, and Great and Little Belts. The Scagerac extends from the Naze of Norway and the north-west point of Jutland, to the Gulf of Gottenburgh and north **Scagerac.** point of Jutland, or Scagen Point, better known to English seamen by the name of the Scaw. The narrowest part of the Scagerac is 19 leagues. The **Cattegat.** Cattegat extends from Gottenburgh and the Scagen Point, to the Sound and Belts. The greatest depth of the Cattegat is 35 fathoms; the depth decreases **Sound.** as it approaches the Sound. The Sound is the channel between the coast of Sweden and the island of Zealand. A mass of rocks on the Swedish shore, distinguishes its entrance from the Cattegat; its termination is between Falsterbo in Sweden, and Cape Stevens in Zealand. Its narrowest part is between Elsineur and Helsingborg, where, measured on the ice, it is 2840 yards. Between Copenhagen and Landscrona, it is between six and seven leagues across. Its greatest depth, where narrowest, is 19 fathoms. Towards the Danish shore, at the entrance of the Sound from the Cattegat, its depth is 16 fathoms; near Copenhagen, not more than four fathoms. Near the Swedish shore, there is a gradual accumulation of sand. The **Great Belt.** Great Belt, between the islands of Zealand and Funen, is between seven and eight leagues broad, at its broadest place, between Corsœr in Zealand, and Nyborg in Funen. The little island Sprogœ lies nearly in the middle of it. The coasts are, in general, low and sandy; the greatest depth is 22 fathoms. **Little Belt.** The Little Belt, between Funen and the coast of Jutland, is, in its greatest breadth, about seven miles, and, where narrowest, about three quarters of a mile. In general, the shores are little elevated. Its greatest depth is 27 fathoms.

Extent of the Baltic. The Baltic extends 240 leagues from Torneo to the island of Wollin, on the coast of Pomerania. Its north extremity is situate in the latitude of 65, 51, and its southern extremity in 53, 30. It goes first in an easterly direction as far as Memel, a length of 300 miles, with a mean breadth of 140. It then goes north to the Aland isles, a length of **Gulf of Bothnia;** 350 miles, with a mean breadth of 70. Its northern portion forms the Gulf of Bothnia, which is 150 leagues in length. Its greatest breadth is 162 miles. The archipelago of Aland lies at its entrance from the Baltic, and forms three channels between the coast of Sweden and these islands. The breadth of the channel is between eight and nine leagues. This is called the Sea of Aland by the Swedes. The space between Aland and the coast of Finland is filled with numerous islands, among which are two channels. The lower part of the Gulf, from Aland to Umeo, is called by the Swedes the *Sea* of Bothnia. Between Umeo and Wasa, the channel is first narrowed by a number of rocky islands, forming a strait eight or nine leagues wide. From hence the Gulf widens very considerably, and to its head is called by the Swedes the *Gulf* of Bothnia. Its greatest ascertained depth is 50 fathoms. On the east, the Baltic forms the Gulf of Finland, which is 80 **of Finland.** leagues long, and from 11 to 22 broad. Its entrance is between Spinthamer Point in Esthonia, and Hangœ Head in Finland. Its greatest depth is 60 fathoms, which, in some places, decreases to five fathoms. A great number of rocky islands, and reefs, many of them level with the water, render the navigation of this sea extremely dangerous.

The general depth of the Baltic is 60 fathoms; **Depth of the Baltic.** but, towards its south-east extremity, and nearly in the middle, are two spots, with 110 and 115 fathoms of water. From the east mouth of the Sound to Bornholm, the depth varies from 9 to 30 fathoms; from thence to Stockholm from 15 to 50; a little south of Lindo it is 60; and among the Aland islands from 60 to 110.

It was long a generally received opinion, that the **Level of its Waters with those of the Ocean,** waters of the Baltic were considerably more elevated than those of the German Ocean, and that they were gradually diminishing. The first opinion seems to have rested entirely on the fact of a constant current setting out of the Baltic. To this it is ascribed by Vice Admiral Nordenancker, who was President of the Swedish Academy in 1792. In a paper published in their *Transactions*, he maintains that, from observations made at different periods, the height of the waters of the Baltic was diminishing at the rate of about four and a half lines annually. Celsius, a learned Swede, towards the middle of the last century, advances the same hypothesis, and, from observations made on the coasts of the Baltic, he estimated the diminution at 45 inches in every hundred years. This hypothesis was supported by Linnæus, who founded on it a theory of the earth; but the chief facts brought forward in support of this opinion, viz. marks on several rocks in the Gulf of Bothnia, and the remains of vessels found at considerable distances from the present shores, by no means warrant it. M. Otto, in his physical observations on this sea, has suggested another theory to account for its apparent decrease. He supposes that, instead of really subsiding, it may be only shifting its position, and gaining in one quarter what it loses in another; and this he ascribes to the large and rapid rivers which carry along with them an immense quantity of earth and sand; and thus the beds at their mouths are raised, and their banks extended towards the sea. **proved.** But recent observations made at the locks of the canal of Holstein prove, that the levels of the Baltic and the ocean are at present generally the same, and

Baltic.

that the trifling differences which may be occasionally observed, are owing to accidental and temporary causes. Hence we may infer, that the constant current setting out of the Baltic, is solely owing to the abundance of the waters which it receives from its rivers.

Tides.

It is generally believed that there are no tides in the Baltic. This, however, is not strictly correct. There are sensible tides in the Scagerac; they begin to diminish in the Cattegat; are very trifling in the Sound and Belts; and in the Baltic, properly so called, are scarcely, if at all, perceptible. There are, however, irregular variations in the level of the waters of the Baltic, which bear some resemblance to tides. These elevations generally occur in autumn, when the weather threatens rain; they last sometimes a few days, sometimes several weeks. The maximum rise is three feet and a half, and the low shores are occasionally inundated. They also render the fresh-water lakes, which communicate with the sea, brackish. In the Gulf of Bothnia, the fall of the waters is usually succeeded by north winds; whereas, near Stockholm, these winds usually follow the elevation. M. Kraft, who was Professor of Experimental Philosophy in the Imperial Academy of Sciences at Petersburgh, in his treatise on the inundations of the Neva at the autumnal equinox, observes, that three or four days before or after the full or new moon, a violent north-west wind drives the waters of the Northern Ocean, during the influx of the tide, into the Baltic, and is accompanied, or immediately succeeded, by a south wind in that sea and the Gulf of Finland. By Schultens, a learned Swede, who paid particular attention to the physical geography of the Baltic, the irregular elevations of this sea are attributed to the state of the atmosphere. He observed, that when the waters are about to rise, the barometer falls, and when they are about to fall, it rises. Hence he inferred, that the unequal pressure of the atmosphere on different portions of the water, deranged the level of the waters. The difference between the greatest and the least rise in the barometer in the northern parts of Europe is two and a half inches, which answers to three and a half feet of water, or the difference of the elevation of the waters at their extremes.

Irregular Variations.

Superior and inferior Currents.

In the Sound there are superior and inferior currents. These were first observed by some Englishmen, who, being in a boat in the middle of the channel, found that they drifted towards the Cattegat; but, having let down a loaded bucket to the depth of four or five fathoms, the boat became stationary; and when the bucket was sunk deeper, the boat drifted against the superficial current. The general currents of the Baltic are strong, and are evidently occasioned by the vast number of rivers and streams that pour their waters into it, many of which, especially towards the north, rise thrice in the course of the year. At the north extremity of the island of Bornholm, a violent agitation of the waters, or kind of whirlpool, called by the Swedes *Malt-quern*, or the grinding-mill, is occasioned by the current rushing over a circular cluster of sunken rocks. The waves of the Baltic are short and broken, in consequence of sudden changes of wind, irregular depths, and strong currents.

Saltness.

The waters of this sea are not nearly so salt as those of the ocean; and when the wind blows strong from the north, they become so fresh as to be fit for drinking or cooking meat. The degree of their saltness varies in different parts, and in the same parts according to the season, or wind. According to Bergman, in his *Physical Geography*, near the south coast of Norway, at the entrance of the Scagerac, the waters contain from $\frac{1}{10}$th to $\frac{1}{7}$th part of their weight of salt: in the Cattegat $\frac{1}{12}$th; in the Baltic $\frac{1}{16}$th; and in the Gulf of Bothnia from $\frac{1}{40}$th to $\frac{1}{30}$th. The south-west and west winds augment the saltness, by introducing the waters of the ocean; in the summer, it requires 300 tons of the water of the Gulf of Bothnia to produce one ton of salt, but in the winter, only 50 tons; this difference is caused by congelation, and by less fresh water flowing into it.

Analysis of its Waters.

The analysis of three pounds of water taken up from the British Sea, on the coast of East Frizeland, and the same quantity from near Rostock in the Baltic, gave

	British Sea.	Baltic.
Muriat of soda -	522	263
Muriat of magnesia	$198\frac{1}{2}$	111
Sulphat of lime -	23	12
Sulphat of soda -	$1\frac{1}{3}$	1
Residue -	$1\frac{1}{2}$	1
	$746\frac{1}{3}$	388

The following are the results of some experiments made by Dr Thomson on the specific gravity of the water in the Firth of Forth, the Baltic off Tunabergh, the Sound, and off the Scaw Point; and also on the comparative weight of salt, obtained from 1000 grains of each of the waters evaporated.

	Specific gravity.	Weight of Salt.
Water of the Firth of Forth	1.02900	36.6
Baltic off Tunabergh	1.00476	7.4
Sound - -	1.00701	11.2
Scaw - -	1.02037	32.0

In the salt obtained from the water off the Scaw, he found

Muriat of soda -	55.7
Sulphat of magnesia -	25.
Muriat of magnesia -	19.3
	100

Wilcke ascertained that the specific gravity of the water of the Baltic was much influenced by the wind.

When the wind was at East, it was	1.0039
— West -	1.0067
— N. W. -	1.0098
Storm at West -	1.0118

Temperature.

There is great difference in the temperature in different parts of the Baltic. The general temperature of the Gulf of Bothnia in July is from 48 to 56, but it is sometimes heated to 70; the medium of the thermometer throughout the year at Uleoborgh, is 29; at Stockholm, the medium is $42\frac{4}{5}$. Near the land in the Gulf of Bothnia, in the month of July, the temperature of the atmosphere was observed to be 68, while the temperature of the surface of the water was 65; and in October, the temperatures were respectively 39 and 46. In the Sound, in the

Baltic.

month of August, the temperature of the atmosphere was 70; on the surface of the water 68; and at three fathoms 66. On the 10th of October 1813, Dr Thomson found the temperature of the Sound to be 54. The Scagerac and Gulf of Norway are open to navigation all the winter, whereas several portions of the Baltic are covered with ice in a very moderate degree of cold; generally the bays and channels are encumbered with ice at the latter end of December. The waters towards the heads of the Gulfs of Bothnia and Finland are first frozen, and the ice being conveyed by the currents to the south, the masses of it are by the increasing cold united into vast fields, which become stationary on the west towards Stockholm, and in the east towards the Islands of Dagœ and Œsel. In the southern parts of the sea, the ice begins to break up in April, but the Gulf of Bothnia and Finland often continue closed till May. The rigour of the climate in the Baltic is supposed to be considerably diminished by the clearing of the forests and the progress of cultivation; at least more intense and longer continued colds, as well as greater extent and solidity of ice, are recorded during the fourteenth and fifteenth centuries, than what have happened latterly.

When Frozen.

Winds.

The winds are extremely variable in the Baltic, but they blow most commonly from the east in the spring, and from the west in autumn; calms are seldom experienced, except in the middle of summer.

Fisheries of the Baltic.

II. There is historical evidence, that the herring fishery was a branch of national industry in the Sound, as early as the year 1168;* and in 1389, Philip de Mezieres says, that such vast shoals of herrings crowded into the Sound, that 40,000 boats, with six to ten men each, were employed in the fishery, besides 900 large vessels, in which the herrings were salted. In the Gulfs of Flensborgh and Slie, besides what are consumed fresh, 1000 tons salted are at present annually exported to Copenhagen and Germany; and, according to the registers of the custom-house at Dalborgh, on the south shore of the Gulf of Limfiord, this city exported yearly, from 1720 to 1730, above 23,000 tons, but from 1754 to 1765, the exportation had fallen to about 8000 tons. In the year 1748, the herring first appeared in shoals in the Gulf of Gottenburgh; at first they arrived in August and September, but gradually later, and at present not till November or December. In 1752, there were 1000 tons taken; in 1753, 2000 tons; in 1761, 100,000 tons; from 1790 to 1796, nearly 2,000,000 tons were salted, and it was estimated that from 50,000 to 100,000 tons were consumed fresh.

Pilchard Fishery.

Pilchards abound in the Gulfs of Bothnia and Finland, into the bays of which they arrive in shoals in spring and autumn. The pilchard fishery is one of the most important branches of industry to the inhabitants on both sides of the Gulf of Bothnia. As soon as the ice breaks up, upwards of 200 families, with their children and servants, transport themselves to the rocks and islets that line the coast, where they remain fishing to the end of autumn. The annual produce of all the pilchard fisheries is estimated at 300,000 tons at least, which are entirely consumed in the Baltic.

Salmon Fishery.

Salmon ascend the rivers from April to June, according as they are free from ice. On the south, they abound most in the Oder, Vistula, Duna, and Narrowa; on the north, in the Motala, Dalecarlia, Uleo, Kemi, Torneo, and Keymen. Salmon trout is taken in some bays of the Baltic. In the middle of the river Kemi is a small Island, where an annual salmon fair is held. The salmon fisheries of Sweden are very considerable both in the Cattegat and the Gulf of Bothnia: from 20,000 to 25,000 tons are salted annually.

Whales and Seals.

Whales very rarely enter the Baltic. The common porpoise is the only one of the lesser species of cetaceous animals that lives habitually in this sea; and at Middlefart, in Funen, is a company, which enjoy the exclusive privilege of taking it. There are two varieties of the common seal, both of which are hunted, in March and April, for their oil, by the peasants of the isle of Gothland, and of the islands in the Gulfs of Bothnia and Finland.

Coasts, &c. of the Baltic.

III. The coast of the Baltic, including under that appellation the Scagerac, the Cattegat, the Sound, and the Belts, as well as Baltic Proper, may be regarded as commencing on the north side at the Naze of Norway. This is the extremity of a rocky peninsula joined to the main by a narrow isthmus; it is surrounded by rocks, of which those named the Bishop and Clerks, five miles to the south of the Naze, are most dangerous to navigators. From the Naze to the East, the shore is formed of elevated barren and dreary rocks. The principal rivers of Norway, which fall into the Scagerac and Cattegat, are the Glommen, the Laugen, the Louen, the Drammen, the Mandal, and the Nid. At the distance of five miles from the Naze is the town of Mandal, situate on the river of that name; from this place is exported a considerable quantity of smoked and salted salmon, esteemed the best in Norway. About 15 miles to the east of this is Christiansand, which has a good roadstead, besides the advantage of the little river Torvedal, to the east of the town; it exports timber, salt, fish, and iron. Arendal, the most secure and capacious harbour in Norway, formed by the Sound between the Island of Fleckerœ and the Main, succeeds. On the river Louen, is the town of Laurwig, which exports a great deal of iron from the founderies in its neighbourhood. The Gulf of Christiana lies

Norwegian Shores.

* "In the year 1238, the inhabitants of Gothia (Sweden) and Frise were prevented, by their fear of the Tartars, from sending, as usual, their ships to the herring fishing on the coast of England; and as there was no exportation, 40 or 50 of these fish were sold for a shilling. (Matthew Paris, page 396.) It is whimsical enough, that the orders of a Mogul Khan, who reigned on the borders of China, should have lowered the price of herrings in the English market."—Gibbon's *Roman Empire*, Vol. XI. p. 422. Note.

Baltic.

some leagues to the east of it. This Gulf runs up into the land 20 leagues, and divides into several branches; the entrance to it is pointed out by the island of Færdar, on which there is a light. The town of Christiana stands at the top of the Gulf; its port will admit the largest vessels, there being from 30 to 40 feet water close to the quay; its exports are fir planks and rafters, pitch, tar, soap, iron, copper, and alum; they generally amount to L. 100,000 annually; the timber constituting four-fifths. There are several little villages on the Gulf, where vessels load with timber. To the east of it is a deep inlet, called Swinesund, which separates Norway and Sweden; it consists of two basins, the outer of which communicates with the inner by a very narrow strait. On the inner basin, and at the mouth of a small river, is Fredericshall, the commerce of which consists principally in the export of planks, sawed by 36 mills on the river.

Swedish Shores.

The Swedish shores of the Scagerac and Cattegat are high, with a most rugged and dreary appearance, particularly near Marstrand, where the shore is lined with steep rocks projecting into the sea. The coast of Schonen forms a striking contrast to the shores of the Scagerac and Cattegat, being nearly level and free from rocks. The Swedish coast from Bleshinghar to the Gulf of Bothnia is lined with Islands and rocks, and broken into a great number of gulfs and bays. Both shores of the Gulf of Bothnia are rugged and broken; that of Sweden, in particular, forms an alpine ridge. The first river in Sweden, towards its western limit, is the Gotha, which empties itself into the Cattegat by two branches surrounding the island of Hysingen. This river, and the Motala, which falls into the Bay of Browick at Nordkœping, are the only rivers of consequence in the southern provinces of Sweden. Between the provinces of Sœdermanland and Upland is the lake Mælar, which communicates with the Baltic at Stockholm by two currents called the north and south; its elevation is six feet above the Baltic. The river Dahl, or great river of Dalecarlia, the Umeo, Torneo, and several others, which rise in the mountains of Lapland and Norway, fall into the Gulf of Bothnia; the northernmost are subject to three inundations annually, the first in March or April, when the snow on the low ground melts; the second towards the end of May, when the snow melts on the more elevated grounds; and the last towards the end of summer, when the thaw has reached the high lands, and dissolved the glaciers. The first commercial port of Sweden of any note is Uddevalla, a staple town; its exports are iron, planks, and herrings. The town of Marstrand, on an island of the same name, succeeds; it is also a staple, and its inhabitants are engaged in the herring-fishery, and in supplying provisions to the vessels that run in for shelter; these exceed 300 annually. The Paternosters are dangerous rocks, some miles north of Marstrand.

Gottenburgh.

On the southern branch of the Gotha, some leagues from the sea, is the city of Gottenburgh; the port is seldom closed by the ice, and is capable of receiving the largest ships; the harbour is about one-fourth of a mile in breadth, and is formed by two chains of rocks.

Before the entrance of the Gotha is the island of Wingœ, with a very high light-house. The south point of the bay of Skelder is formed of a mass of rocks, lying at the entrance of the Sound, named Kullen; this mass projects far into the sea, and on the highest point, 200 feet above the sea, is a fire tower. On the Swedish shore of the Sound are several villages of little consequence. Helsingburgh, which is the usual crossing-place to Elsineur, is the only one deserving of notice. Four leagues to the southward is Landscrona, a small and ill-sheltered port, with 20 feet water; it is a staple town. The next port is Malmoe, which has a considerable trade, though its harbour is not capable of receiving vessels of any considerable burden. To the south are Skanor and Falsterbo, on the peninsular point, which forms the entrance of the Sound from the Baltic. Close to the latter is a fire tower, to direct vessels clear of a large reef, which runs off from the point. The first Swedish ports on the Baltic of any consequence are Christianstad and Carlshamn; the first is situated on the Helge, which empties itself into a gulf that separates the provinces of Schonen and Blekingen; the latter has 40 trading vessels engaged in foreign voyages; its principal export is potash, which is esteemed of superior quality. They are both staple towns. The principal part of the town of Carlscrona is built on the Island of Trosœ; the rest of it on several rocky islets joined to the main by bridges. It is a staple town, and has about 40 vessels employed in foreign trade; the port is capable of holding 100 sail of the line; on one of the islands is a dock for four sail of the line. Carlscrona is the principal station of the Swedish navy. The Strait of Calmar, which is from two to three leagues broad, separates the mainland from the Island of Œland. Near the middle of the strait stands the town of Calmar, which, though not a staple, has a considerable trade, and vessels from 100 to 300 tons belonging to it. North of Calmar are several small towns on the coast, one of which, Westerwic, has some shipbuilding. In East Gothland, the province which lies to the north of Smaland on the Baltic are two considerable gulfs, Slœtbacken and Browick. On the river Motala, which falls into the latter, stands the staple town of Nordkœping, from which are exported considerable quantities of iron, iron-cannon, and copper, though its port can receive vessels only of light burden. From 300 to 400 enter it annually; 30 or 40 trading vessels belong to it. North of the entrance of a Sound, which communicates with lake Mælar by a canal, is Landsort Island, where is a light, and from whence ships take pilots for Stockholm.

Helsingburgh. Carlscrona.

Stockholm.

Stockholm is built on seven or eight islands and peninsulas, at the entrance of Lake Mælar; the channel is 12 leagues long, very winding, and terminates in a basin capable of holding 1000 ships. The largest island, on which the city stands, forms two channels, through which the waters of the lake rush out with great impetuosity.

The only ports of any consequence in the province of Upland, are Grislehamn, opposite the islands of Aland, where travellers embark or take sledge for Abo, and Œregrund, on an island in the channel of Aland, from which the iron from the founderies of

Baltic.

Danemora is exported: formerly it went chiefly to England, where it was converted into steel. From Gefle, a staple town on both sides of a river of the same name, are exported considerable quantities of iron, planks, tar, and potash; its imports are corn and salt. The smaller islands in the Baltic, belonging to Sweden, have already been noticed; besides them there are Huen, Œland, and Gottland. Huen lies in the Sound, four miles from Landscrona, three from the nearest point of Sweden, and four from the nearest point of Zealand; it is about six miles in circumference. Œland is separated from the coast of East Gothland by the Strait of Calmar; the east coast of the island is bold and clear, but the west is dangerous for mariners. Between Œland and a group of rocks, is the southern channel into the Strait of Calmar. Nearly in the middle of the strait is a rock, almost perpendicular, 240 feet high, surrounded by reefs. Gottland, which is 18 leagues from the nearest point of Sweden, and about the same distance from Courland, is 20 leagues long, and seven at its greatest breadth. The shore of it, in some places, is nearly perpendicular, in other places, it ascends gradually. Wisby, the capital, is built on the west coast; at present its port can receive only a few small vessels. Slitehamn, on the east of the island, is one of the best ports in the Baltic, and is defended by the fort of Carlsbelt.

Swedish Islands.

The coasts, rivers, gulfs, and principal commercial ports of the south and east of the Baltic, are next to be described; and, beginning at the entrance from the German Ocean, those of Denmark first present themselves. The north point of Jutland, in the Scaw, is surrounded by a reef several leagues in extent, and on its extremity is a light-house, 64 feet above the level of the sea. The north and east coasts of this peninsula are generally low; the northern extremity is composed of sands, which are often conveyed by whirlwinds to a great distance, and do considerable damage. In order to fix them, a variety of plants, particularly the *Elymus arenarius*, sea lime-grass, are sown. The east coasts of Sleswick and Holstein descend gently to the sea. On all these coasts there are numerous gulfs and bays; the first towards the north, is the Limfiord, which nearly divides the peninsula of Jutland, being separated from the German Ocean only by a sandy isthmus, three or four miles broad; another arm of it advances southward to the town of Wybourgh, a length of about 80 or 90 miles; its entrance is two miles wide, but afterwards it becomes greatly wider; sands that very sensibly increase, and masses of granite, obstruct its entrance. In Jutland, there are also the Gulfs of Mariager, and Randers, and several bays. In Sleswick, on the Baltic side, are the Gulfs of Colding, Flensborgh, and Slie, which resembles a great river, and Ekernefiord; in Holstein are the Gulfs of Kiel, which separates this province from Sleswick, and of Lubec, and the bay of Colbergh. The Guden is the chief river in Jutland, which falls into the Baltic, at the Gulf of Randers, after a course of 40 miles; its navigation has been recently improved.

Coast of the Danish Peninsula.

Gulfs and Bays.

Ports.

From the Scaw to the entrance of the Gulf of Limfiord, there are only small towns, chiefly inhabited by fishermen and pilots. On the north shore of the entrance of Limfiord is the fort of Hals, where vessels, of too great depth to ascend higher, discharge their cargoes; on the south shore, four leagues and a half from the sea, is Aalborg, the chief town of Jutland. It possesses considerable commerce, its exports being corn, cattle, and fish, and 60 or 70 trading vessels belonging to it. Frederica, which stands on a promontory at the entrance of the Little Belt, has an inconvenient and badly sheltered port; the merchant-vessels passing through the Little Belt pay toll here. Colding, at the head of the gulf of the same name, which separates Jutland and Sleswick, is a commercial town, and has a port of two miles in circuit, and of depth for the largest vessels. The trade of Sleswick, which stands at the head of the gulf of Slie, has much declined: the entrance to its port being filled up with sand, a canal has been cut into it.

Danish Islands. Zealand.

Of the Danish islands, Zealand is the principal; its length is 24 leagues, its breadth varies from 20 to 14; the Gulf of Isefiord, divided into two branches, penetrates the north side of it; at the entrance to which there is nine feet water, but it deepens within to seven fathoms. The most remarkable river in Zealand is the Nesaa, which nearly traverses it, and enters the Baltic. Elsineur, on the narrowest part of the Sound, has only a roadstead; here the duties of the Sound are paid. The origin of these duties may be traced to the middle-ages, when they were established by the sovereigns of Denmark for the support of light-houses, and the protection of the navigation of the Baltic from pirates. These duties vary from 450,000 to 600,000 rix-dollars annually. The mails and passage-boats cross the Sound from Elsineur to Helsinburgh.

Duties of the Sound.

Copenhagen.

Copenhagen is built partly on the mainland, and partly on the island of Amak, which is separated from it by a narrow channel, crossed by two bridges. The port between Amak and the main, is one of the best in the Baltic, both by nature and art. Within are basins capable of holding 500 sail, but the entrance admits but one ship at a time. There are two royal dock-yards constructed on islands, where every ship has her particular magazine; the dry-dock is constructed of wood, and requires 20 hours to pump it out, which is done by horses. Copenhagen is a free port, and for a long time was the only one in Denmark which enjoyed the privilege of importing the produce of Iceland, Greenland, India, China, and America; and, even yet, the principal returns from these countries are made to it.

The Islands of Mæen, &c.

Mæen island is separated from the south-east end of Zealand by Ulfsund, a narrow strait; it is about five leagues long, and from one to three broad. It exports 15,000 tons of corn. Samsœ, midway between Zealand and Jutland, is near five leagues long, and is formed of two peninsulas, the largest of which is five miles broad. The other islands belonging to the government of Zealand are of little consequence. Saltholm, in the Sound, may, however, be particularized; it is four miles long, and two broad; almost covered by the sea in winter, but in summer affords good pasturage; from it are exported to the capital, marble, freestone, and lime.

Funen.

Funen, the second of the Danish islands in extent,

Baltic.

is 16 leagues long, and 11 broad. The Gulf of Odenzee runs considerably into it on the north-east. At the head of it stands the town of Odenzee, the capital. From twenty to thirty trading vessels belong to it. At Nyborg, on the Great Belt, a duty is paid by all merchant vessels passing through; it is also the usual crossing-place to Zealand, and has a good port, and about as many vessels belonging to it as Odenzee. The island of Funen exports corn, and, in the year 1799, there belonged to it fifty-seven vessels above 20 tons; containing 2522 tons, with 109 men. From Rudkæbing, the only town on Langland, an island between Funen and Zealand, corn, salted meat, hides, honey, and wax are exported.

Laaland.

Laaland, the third of the Danish islands in size, is 11 leagues long, and from six to eight broad. Considerable portions of its coast are so low as to be inundated during the irregular elevations of the sea. The feathers of aquatic birds and corn are its principal exports. From this island Falster is separated by Guldborg Sound, and from Mæen by Grensund. It is eight leagues long, and from one to four broad. It exports corn and fruit. In the year 1799, there were in the bailiwick of Laaland and Falster fourteen vessels, of 460 tons and 40 men. In the government of Jutland, are the Islands of Lessœ and Anholt, in the Cattegat; the latter is surrounded by dangerous banks.

Bornholm.

Bornholm is an island about seven leagues and a half from the coast of Sweden, and upwards of 17 from the island of Rugen; it is eight leagues long, and five and a half broad. Its shores are composed of steep rocks, surrounded by dangerous reefs. The principal imports are coffee, sugar, and tobacco; the principal exports are salted cod, corn, poultry, and clay for the porcelain manufactory of Copenhagen, and freestone for its public buildings. The centre of commerce is at Ronne, near the middle of the west side of the Island. In 1800, this place employed 60 vessels and 130 boats, chiefly in the fisheries.

Coasts, &c. of Holstein and Lubec.

The first shore on the south of the Baltic is that of Holstein, the principal port-town of which is Kiel, a place of considerable commerce. The territory of Lubec succeeds. The city of Lubec is situate on the Trave, five leagues from its mouth. Its commerce is chiefly transit, and on commission, drawing from Russia, Sweden, and Denmark, their raw commodities, and supplying them with wines, silks, cloth, hardware, and colonial goods. It admits vessels of from 150 to 200 tons. In 1802 it had from 70 to 80 merchant vessels, and the same year 1368 entered, and 1234 cleared out. Travemunde, on the mouth of the Trave, about nine miles from Lubec, is the port where vessels destined to and from Lubec take their station. The Trave, near Lubec, is joined by the Wakenitz, which, issuing from the Lake of Ratzeburgh, thus facilitates the water communication between Lubec and the interior.

Mecklenburgh.

On passing the Trave, the duchy of Mecklenburgh is entered. Wismar, a bay within the isle of Poel, and Rostock, on the left bank of the Warnaw, three leagues from its mouth, are the principal commercial places in Mecklenburgh. The exports from the latter are corn, hemp, flax, hops, wax, butter, honey, cattle, apples, and feathers.

Coast of Pomerania.

The coast of Pomerania exhibits the effects of the constant action of the waters of the Baltic. On the west, the peninsula of Dars, and the Island of Zingst, form the basin called *des Dars*, which has six feet depth. The Strait of Gellen, farther east, separates the Island of Rugen from the main. This strait varies in breadth from fourteen miles to one and a quarter; the eastern entrance, called the Bodden, is navigable for the largest vessels; but in the narrows there is but three or four fathoms; and the sand accumulates so fast here, as to require a toll on all vessels passing through it, to defray the expence of clearing it.

Prussian Coasts.

The Gulf of Dantzic lies beyond the eastern limits of Pomerania, the western extremity of which, called the Gulf of Putzic, is formed by a curved tongue of land. On the coast of Prussia are the two remarkable basins called the Fresch-Haff and Curish-Haff. The waters of both are fresh, being supplied from the rivers of Poland, and each communicates with the Baltic by a single strait. The Fresch Haff, which, besides three branches of the Vistula, receives the rivers of Elbing, the Passarge, and the Pregel, is 16 or 17 leagues long, and from one to five broad. The communication of this basin with the Baltic has changed several times, and the present passage, near Pillau, was formed by a great storm in 1500; its depth is from 13 to 16 feet. The tongue of land called the Fresch-Nehrung, which separates it from the Baltic, commences near Dantzic, and runs east about 19 leagues; its breadth varies from one to three leagues. The Curish-Haff, or Sea of the Cures, a people of Courland, is 19 leagues long, and from one to three broad. Its depth is very irregular, and there are many sandbanks in it. Near the upper end there is no current, but in the other parts the currents are very rapid. It communicates with the Baltic by a channel near Memel 3200 feet wide, and from 11 to 13 feet deep. The spit of land which separates it from the Baltic, called the Curish-Nehrung, is about 80 miles long, in some places three miles broad, but in other places is so very narrow, that the waves of the Baltic wash over it into the basin. Its surface, which is principally sand, continually changes, by the fury of the winds. From its ancient name Mendoniemi, or promontory of Pines, it was probaby covered with those trees. It is inhabited only by fishermen and pilots, whose dwellings are not unfrequently overwhelmed by the sand. It is frequented by immense numbers of crows and hawks, the former of which supply food to the inhabitants, and the tithe of them forms part of the revenue of the pastor.

Gulf of Livonia.

The whole coast of Prussia and Courland is low, sandy, and covered with pebbles; the latter, however, has calcareous cliffs, which seem to run under water to the Island of Gottland. The Gulf of Livonia, or Riga, has Domes-ness for its southern limit; between which and the Swaverort is the entrance, eight leagues wide; but from Domes-ness a sandbank runs off, and a reef from Swaverort. The coast of Livonia, and the islands off it, are in general higher than those of Courland, and are composed of sand, gravel, and calcareous strata. Entering the Gulf of Finland, on the south side, is the bay of

Baltic.

Roggerswic, inclosed by islands. The whole of the coast of Finland is naked, stony, lined with rocks and islets, and nearly bare of vegetation.

Rivers of Prussia.

The principal rivers of Prussia that flow into the Baltic are the Oder and the Vistula. The Oder, after dividing into four principal branches, near the frontiers of Pomerania, again flows in one stream near Stettin, and falls into the Gros-Haff. Between the Oder and the Vistula several lesser rivers empty themselves; they are generally navigable, and form ports at their mouths. Three of the branches of the Vistula empty themselves into the Fresch Haff, and the fourth, which alone retains its original name, falls into the Gulf of Dantzic at Weixelmunde. The Pregel, which is deeper than the Fresch Haff, into which it falls, is navigated by vessels of considerable burden. The Elbing issues from Lake Dramsen, and, as has been already noticed, falls into the Fresch Haff. The Niemen, below Tilsit, separates into two branches, one running to the south-west, and the other to the north-west; thus both subdivide, and fall into the Curish-Haff near Memel; the Dange, which gives a port to Memel, has a short course, but is wide and deep.

Ports on the Pomeranian Shore.

Stralsund is the first commercial port on the Pomeranian shore of the Baltic. Its harbour is inclosed by jetties, but its access is dangerous and difficult, on account of sand-banks. It has a considerable export trade in brandy, starch, and linens. Stettin, on the Oder, succeeds. Vessels of moderate burden go up to it, but large ones discharge at Swinemund, on the channel into the Gros-Haff, which separates the Islands of Usedom and Wollin. Between the years 1787 and 1796, the annual or whole exports were 3714 tons. The imports are manufactured goods from England, salt, wines, and fruits from France, &c. and linseed from Russia. About 160 vessels, manned by 1000 seamen, belong to it. From Politz, near the mouth of the Oder, are exported several thousand bushels of hops, chiefly to Sweden.

Islands.

The principal islands off the coast of Pomerania are Rugen, Usedom, Ruden, and Wollin. Rugen is separated from the mainland by the Strait of Gellen. It is of a very irregular shape, and consists of the Island Proper, and three peninsulas. It is supposed to contain 142,000 acres. Two of the peninsulas terminate in promontories, composed of chalky cliffs, one of which is 430 feet high. There is no port on the island, but from the roads are exported herrings, cattle, corn, and salted geese. The coasts are very dangerous, scarcely a year passing in which several vessels are not stranded, and several ancient regulations are still in force respecting the assistance which the inhabitants are bound to give in case of shipwrecks. The islands of Usedom, Ruden, and Wollin, are formed by the alluvium of the Peene and the Oder; they are very low, and in general sandy.

Ports in Prussian Poland-Dantzic.

Dantzic is the principal commercial place in Prussian Poland. It is situate on the western branch of the Vistula, five miles from its mouth, and at the confluence of the rivulets Motlau and Radaune. These form its port, to which there is an entrance by a canal giving a new channel to the Vistula, the old one being choked up. Dantzic has long justly been considered as one of the principal granaries of Europe. Its annual exports of corn average about 700,000 tons. Its other exports are timber, beer, brandy, horse-hair, hogs'-bristles, feathers, wool, amber, honey, wax, linens, masts of ships, cork-wood, hemp and flax, potash, salt, tar, skins, fruits, &c. Its imports are English manufactures, and London porter, herrings, fruits, lead, coffee, tea, sugar, indigo, wines, &c.

Pillau.

Pillau, whence there is a considerable export of timber, stands on a peninsula washed by the Fresch-Haff on one side, and the Baltic on the other. From Koningsbergh, on an island at the mouth of the Pregel, are exported nearly the same articles as from Dantzic, in between 600 and 700 vessels annually. From Elbing, at the mouth of the river of the same name, corn, starch, linseed-oil, soap, cordage, sail-cloth, saltpetre, potash, and timber, are exported in between 300 and 400 vessels annually. The port of Memel, formerly the mouth of the river Dange, is liable to be encumbered with mud; its chief exports are, ship-timber, masts, linseed of a superior quality, hemp, flax, hides and tallow.

Koningsbergh.

Elbing.

Memel.

Russian Rivers in Courland and Livonia,

The first Russian river of consequence that falls into the Baltic is the Western Dwina. It is navigable from its source to within a few miles of Riga, where ridges of rocks form fourteen falls. These, however, do not prevent the floating down of immense quantities of timber. It is frozen from the end of November to the beginning of April. It separates Courland from Livonia, and, after a course of 180 leagues, falls into the gulf of Livonia before Riga. The Narrowa, which is the only outlet of Lakes Peipus and Plaskoff, falls into the Gulf of Finland at Narva, but its navigation is obstructed half a-league above that town by a fall. The Neva, which issues from Lake Ladoga, empties itself by several branches at Petersburgh, above which it is from 150 to 200 fathoms broad. It is shallow, and is frozen from the end of October to the end of April. The principal rivers in Finland are the Wuoxen, which falls into Lake Ladoga; the Kymene, into the Gulf of Finland; and the Kumo, Uleo, Kemi, and Torneo, which fall into the Gulf of Bothnia, at the towns of their respective names. In Courland, Russia has only two ports of any commercial consequence, Liebau and Windau. From the former, on a river of the same name, in the year 1800, 111 vessels cleared out, and 113 entered it; and the value of its export was 1,065,700 rubles, and of its imports 620,000. Riga and Pernau are the principal ports in Livonia. Riga is one of the most commercial cities of the Baltic, and the second of Russia in this respect. Its port can only receive small vessels, large ones being obliged to lie in the roads. The exports consist of corn, hemp, flax, ship-timber, pitch, potash, hides, tallow, iron, &c. The imports are woollen and cotton goods, hardware, wines, oils, and spirits, and colonial produce.

in Finland.

Ports in Courland,

Riga.

in Livonia.

Revel.

Though the entrance to Revel is through dangerous shoals, and it stands on a river which affords little or no intercourse with the interior, yet its commerce is considerable. Its exports and imports are nearly the same as Riga.

Petersburgh.

Petersburgh is built on both sides of the Neva, and on several islands. The mouth of the river being choked by sand, there are only from seven to eleven

Baltic.

feet water over it, according as the wind blows from the east or west. With easterly winds, the river often falls three or four feet below its general level; whereas westerly winds sometimes raise it from ten to fifteen feet. Loaded ships, of any considerable burden, cannot, therefore, approach the city within four miles. The principal exports are, iron, hemp, flax, cordage, tallow, hides, linseed-oil, hemp and flax-seed, planks and rafters, leather, soap, candles, wax and honey, fish, caviar, tobacco, rhubarb, tea, isinglass, feathers, linen, and furs. The principal imports are English cotton manufactures, French wines, colours, coffee, sugar, drugs, &c.

Cronstadt.

Cronstadt, the principal station of the Russian fleet, is built on a little island on the Gulf of Petersburgh, four leagues below the city, the same distance from Ingria, and nine leagues from Finland. The channel to the capital is between this place and the coast of Ingria. Its navigable breadth is three quarters of a mile, its depth four fathoms. The channel between Cronstadt and the coast of Finland has only five feet water. Cronstadt has three havens, two for ships of war, and one for merchant vessels. The dry-docks, which communicate with the sea by a canal, require nine days to empty them. The principal man of war's port has space for 30 sail of the line.

Ports in Finland.

The first commercial port in Finland is Wyborgh, built on a peninsula in a gulf of the same name. It exports corn, butter, tallow, fish, fish-oil, salted provisions, timber, tar, and hops. In 1793, the value of the exports was 124,832 rubles, and of the imports 120,000. Helsingfors, the best port in Finland for large ships, is on a bay, and opposite to it is Sveaborg, the Gibraltar of the north. It occupies seven Islands, and has two basins for repairing ships of the line and smaller vessels. At the entrance of the Gulf of Bothnia, on a peninsula, stands Abo. Vessels drawing nine or ten feet go up to the town. While it belonged to Sweden, it was a staple town, with some trade to the Mediterranean, France, and Holland, whither it exported iron, nails, copper, deals, rafters, pitch and tar, salted provisions, hides, furs, coarse linens, and firewood to Stockholm and Copenhagen. From Abo there is no commercial place of consequence till we come to Gamla Carlby, which, in 1794, had 14 ships, of 1530 tons, thirteen of which were employed in foreign trade. Its exports that year were 1800 barrels of tar, 1500 of pitch, between 3000 and 4000 deals, 2000 lbs. of butter, 273 cwt. of tallow, and 900 barrels of corn. Brahested, a staple town, while Finland belonged to Sweden, possesses commerce nearly of the same kind and to the same amount as Gamla Carlby. It lies in a bay between two peninsulas. Uleoborg, the chief town of East Bothnia, on the Uleo, exports annually a considerable quantity of pitch and tar, butter, tallow, salmon, pike, herrings, and deals. On the Islands at the mouth of the river are two building places, from which five or six ships are launched annually. Torneo is situate on a peninsula, and had formerly a good harbour, but the accumulation of sand has almost spoilt it. The exports, besides the general articles from the other ports of Finland, are salted and smoked rein-deer flesh, and the furs of the rein-deer, fox, wolf, and ermine, procured from the Laplanders who visit the town once a year.

Russian Islands.

The Russian islands at the north extremity of the Gulf of Livonia, Œsel and Dagœ, and the numerous Islands and rocks in the Gulf of Finland require no particular notice. The Archipelago of Aland, which was ceded to Russia along with Swedish Finland in 1809, is composed of one considerable, and above 80 lesser islands and rocks. They are in general elevated, rising in rocky peaks, with numerous caverns. The principal island is nearly round, and 20 leagues in circumference. There is no town on any of them. Besides firewood, 12,000 loads of which are sent annually to Finland and Sweden, the inhabitants export salted beef, seal-skins and oil, tallow, hides, pilchards, and butter, chiefly to Stockholm.

Canals of the Baltic.

IV. The commerce of the Baltic is considerably facilitated and increased by means of different canals, that form a communication with different parts of it, with it and other seas, and with the interior of the countries, the shores of which it washes.

Holstein Canal.

The ancient Scandinavian chronicles mention a natural water communication between the Baltic and the German Ocean, through the Danish peninsula, by means of the Gulf of Kiel, the river Lewensaw, the Lake Flemhud, and the river Eyder. When the communication ceased to be practicable, an attempt to renew it was made in the middle of the seventeenth century by the Duke of Holstein Gottorp. It did not however succeed, in consequence of the opposition of the King of Denmark. The union of Holstein and Denmark taking place in 1773, the proposed canal was begun in 1777, and finished in 1784. It enters from the Baltic by the Gulf of Kiel, near the mouth of the Lewensau, the waters of which serve to supply it. It then joins the northern extremity of Lake Flemhud, joins the Upper Eyder, passes by Rendsburgh, and falls into the German Ocean at Tonningen. The perpendicular fall towards the Baltic is 25 feet 6 inches; and that towards the ocean 23. To Lake Flemhud, which is the highest point, the vessels are drawn by horses, and elevated by three locks of nearly 10 feet fall each: three other locks lower them to the Eyder; from Rendsburgh to Tonningen the vessels use their sails. The whole length of the navigation, from sea to sea, is about 105 miles, of which the canal is about 20½; the breadth is 100 feet at top, and 54 at bottom; the least depth is 10 feet, so that it can admit vessels of about 140 tons burden. Upwards of 2000 pass it annually.

Canal of Stecknitz.

The Baltic and the German Ocean are also united by means of the canal of Stecknitz. This canal unites the rivulet of that name, which falls into the Trave with the Devenau, a rivulet emptying itself into the Elbe at Lauenborg. This navigation is fit only for flat-bottom boats, and is very tedious.

Of Muhlrose and Finow.

The Baltic has communication with the interior of Germany, by the canals of Muhlrose and Finow. The first unites the Oder above Frankfort, with the Spree, one of the tributary streams of the Elbe. The canal of Finow joins the river of this name, which falls into the Oder, with the Havel, another branch of the Elbe. By means of these and some lesser canals, a

Baltic.

long navigation through Silesia, Brandenburgh, Lower Saxony, and Pomerania, is maintained. There is also an artificial navigation which unites the Vistula and the Oder; this is the canal of Bromberg, which joins the Brahe, a tributary of the Vistula, with the Netze, which falls into the Warthe, and the latter into the Oder. The Niemen, in conjunction with the Dnieper, affords a communication between the Baltic and the Black Sea; the canal of Pinsk uniting the former river near its head, with the Priapetz, which empties itself into the Dnieper. These seas are also united by means of the Dwina and Dnieper. The boats employed in this navigation ascend the Dwina to the Ulla, which they also ascend as far as the Lake Beloie, out of which it flows. By crossing this lake, they reach the river Essena, which they ascend to Lake Beresina. Here they enter a canal four leagues long, which conveys them into Lake Plawia. From this lake the river Sargutsch flows, which joins the river Beresina, and this latter falls into the Dnieper; but the cataracts in this river, about 250 miles above its estuary, greatly impede the intercourse that might otherwise be established by these two navigations, between the Baltic and the Black Sea.

[Canal o]f Bromb[erg.]

[Canal o]f Pinsk.

[Ca]nals of [La]doga, &c.

The Baltic and Caspian Sea are united by the canals of Ladoga and Vyschnei Volotschok. The canal of Ladoga, so called, not because it enters that Lake, but as winding along its margin, extends from the river Volchof to the Neva. In the original navigation, the boats passed from the canal of Ladoga up the Volchof to Lake Ilmen, and from this lake entered the river Masta; but in consequence of the fatal accidents that happened on the rapids of this river, one of which is six or seven leagues long, a canal was cut directly from the Volchof to the Masta above the rapids. The old route is here only followed at a certain season, and by boats of a peculiar construction. Ascending the Masta, the boats enter the Lake Mstinskoja, and thence the river Shlina, from which, by means of a canal with a lock, they enter the Sna, and by another lock the canal of Vyschnei Volotschok. This is a league in length, and from it a lock lowers the boats into the Twerza, which they descend to the Volga. In order to facilitate the ascending navigation from Petersburgh, which is rendered tedious by the rapidity of the Volchof and the Masta, a canal has been cut combining the Tichwin, which falls into the Lake Ladoga and the Somina, which falls into the Molaga, a tributary of the Wolga. In spring the vessels may draw two and a-half feet water; but in summer only 26 inches. In autumn, the navigation from Vyschnei Volotschok to Petersburgh is performed in rather more than a month; in summer, in three weeks; and in spring in a fortnight.

By these canals a navigation is established nearly the whole way from Petersburgh to the frontiers of China, there being an interruption only in two places, both not more than 60 miles. The distance from Petersburgh is between 1600 and 1700 leagues; but the rivers being navigable only in the fine season, it requires three years to complete the passage. The extent of the commerce is about one and a-half million of rubles annually.

[M]aria.

The Baltic and the Caspian are also connected by the canal of Maria. The boats ascend the Neva, cross the Lake Ladoga, and enter the Swir, which they ascend to Lake Onega. From this Lake they ascend the Wytegra, which is united by the canal of Maria to the Kowska. By ascending this, they arrive at Lake Bieloe, crossing which they enter the river Tchesna, which they descend to the Wolga. A canal has long been projected to form a communication between the Baltic and White Sea; but though it was begun nearly forty years ago, there is only a short cut of about seven miles executed.

Canals in Sweden.

Ever since the time of Gustavas Vasa, the Swedes have been anxious to form an inland navigation between Stockholm and the Cattegat, principally in order to avoid the payment of the duties of the Sound, and Danish privateers in case of war. This navigation presented no very formidable difficulties. The Gotha flows out of Lake Venar; this is at no great distance from Lake Hielmar; and this is still nearer Lake Mælar, which communicates with the Baltic at Stockholm. Hence, it appears, that the plan of forming an internal water communication between Gottenburgh and the capital, may be divided into three principal parts: the junction of the Hielmar and the Mælar; of the Hielmar and the Venar; and the rendering the Gotha navigable from the Venar to Gottenburgh. The Hielmar is 73 feet higher than the Mælar, which is six feet above the Baltic. These two lakes were united in the reigns of Christina, Charles XI. and Charles XII., by the small river Ulvison, and the canal of Arboga. Nine locks are necessary to establish this communication. The junction of the Hielmer and Venar has been attempted, only very lately, with any hopes of a successful and speedy termination. The obstacles that opposed the navigation of the Gotha from Lake Venar, were principally just at its first issuing from that lake, at the four cataracts, 20 leagues above Gottenburgh, called by the general name of Trollhæta; the fall of Akerstream, about a mile below these cataracts, and a bed of rocks at Edit, considerably nearer Gottenburgh. The first impediment was removed in the reign of Charles IX. and XII. by the Carlsgraf Canal. Attempts were made to remove the second by carrying a canal along the channel of the river; but these not succeeding, it was resolved to cut the canal through the solid rock that forms its banks. This work was begun in 1793, and in seven years it was completed. The canal commences below the first fall of Trollhæta (for this fall, by the former plan, had been nearly turned into still water), and is carried nearly a league before it again joins the river; its breadth is 22 feet, and its depth six and a-half; it has eight locks, and a large reservoir. A communication between Lake Mælar and the lake Sodra Barken on the borders of Dalecarlia, is effected by means of the canal of Stræhmsholm, some small lakes, a river, and several locks, some of which have a fall of 38 feet. A communication between Lake Mælar and the Baltic, considerably to the south of the exit of that lake, and much shorter than by it, is afforded by means of a canal that joins Lake Mælar with the Sound, at the head of which stands the town of Sœder Telje.

It is also proposed to form a communication be-

Baltic.

tween the Cattegat and the Baltic, by means of the Gotha, the lakes Venar and Vetter, the river Motala, and a canal. Between these lakes are several intermediate waters, which will facilitate the communication; the Vetter empties itself by the river Mottala, which enters the Bay of Browick at Nordkœping; but, in consequence of the falls and other obstructions of this river, it will be employed only part of its course, in the intended navigation, which will be completed by a canal to the Gulf of Slœtbacken, at Sœderkæping.

Commerce of the Baltic.

V. In proportion as the maritime nations of Europe increased their navy, the commerce of the Baltic, which supplied them with flax, hemp, iron, pitch, tar, timber, and masts, flourished and extended. England and France filled their arsenals with marine stores from the Baltic; and the Dutch formed immense depots of them, not only for their own use, but to supply the nations of the south of Europe. The stimulus to the commerce of this sea was reciprocal; for the nations on its shores began to acquire a taste for the luxuries of life, wines, spices, fine woollens, cottons, silks, sweet oil, fruits, tobacco, coffee, sugar, and expensive furniture. Towards the middle of the seventeenth century, 2000 vessels passed the Sound annually. Light-houses and beacons were multiplied, companies of pilots were formed, and tribunals of commerce, banks, and exchanges, were established in the principal cities. Christian IV. was particularly distinguished for accelerating the commercial progress of Denmark at this period, though, by his war with Sweden, he weakened and diminished his territories. From the reign of Eni XIV. Sweden had gradually extended her influence and her commerce on the Baltic. Charles IX. subdued a great part of Esthonia and Livonia, built towns in Finland, and founded Gottenburgh. Gustavus Adolphus built several towns on the Gulf of Bothnia. Charles XI. encouraged the building of merchant vessels, and paid great attention to the improvement of roads and the formation of canals.

Soon after this, another maritime power appeared on the shores of the Baltic. Frederick William, the Great Elector, having acquired a part of Pomerania, and formed Prussia into an independent state, turned his attention to commerce. He attacked Sweden, annoyed her commerce, organized the ports of Prussia, and deepened and provided with pilots those of Memel, Elbing, Koningsbergh, and Pillau.

At the beginning of the eighteenth century, Russia, under Peter the Great, began to participate in the commerce of this sea. Esthonia and Livonia were united to his dominions, and Petersburgh was founded. The first foreign vessel that entered the Neva was a large Dutch ship, richly laden; and her arrival gave Peter so much pleasure, that he granted her an exemption from all duties so long as she should continue to trade to Petersburgh; and, by frequent repairs, she was kept in existence for more than half a century. So early as 1718, 100 Dutch ships loaded at Petersburgh, and other nations soon followed their example. In the middle of the eighteenth century, the exports of Russia from the Baltic amounted to twelve or thirteen millions of rubles, and her imports to about eight or ten.

During the wars which arose out of the French revolution, the commercial relations and resources of the Baltic nations have undergone a considerable change by the transference of Swedish Pomerania to Prussia; of Swedish Finland to Russia; and of Norway to Sweden. The effects which these transferences will produce, cannot yet be ascertained.

The following statements and tables, will exhibit a view of the commerce of the Baltic nations at the close of the last, and the commencement of the present century.

Danish Commerce.

The Danish vessels visit the ports of Mecklenburgh and Pomerania, with horses, bullocks, butter, cheese, fish, fish-oil, colonial produce, &c.; and receive in return, thread, linen, brandy, wool, hardware, paper, &c. To Petersburgh, Riga, and Memel, the Danes send herrings and dried fish, woollen manufactures, salt of France, Spain and Portugal, India and China goods, oysters, and dog-skin gloves; for which they receive potash, planks, fire-wood, flax, and hemp, cordage, iron, copper, linens, and corn. To Holland, Denmark exports rape-seed, salted and dried fish, and timber; and receives spices, drugs, corn, pipes, and paper. To England, hides, bar-iron, kelp, furs, tar, timber, &c. The returns are, hardware goods, woollens, cottons, hats, and colonial produce. From the official account of the real value of the imports into Denmark from Great Britain, from the 5th January 1798, to the 5th January 1808, laid before Parliament, in consequence of the attack on Copenhagen, it appears, that from 1798 to 1803, they are rated about half a million; and that from 1803 to 1808, they varied from two to six millions. France receives from Denmark, horses, butter, cheese, fish, &c.; and returns salt, wines, brandy, fruits, silks, &c. The exports to Spain and Portugal are nearly the same as to France; the imports also are the same, with the addition of wool and American produce. To the Mediterranean, Denmark sends fish, salted provisions, butter, iron, &c.; and receives wines, brandy, oils, fruit, and salt. The Danes derive great profit from hiring their vessels to the ports of Italy, as their flag is generally respected by the Barbary States. The exports to the Farœ Islands are wheat, flour, brandy, tea, coffee, sugar, linens, &c.; the imports are dried and salted fish, fish-oil, feathers, hides, tallow, and worsted stockings. The exports to, and imports from Iceland, are nearly the same; the imports from Greenland are whale-oil and bone, seal-oil and skins, eider down; the exports nearly the same as to the Farœ and Iceland Islands. Denmark has also a trifling trade to the East and West Indies.

State of the Danish merchant marine at different periods.

	No. of Vessels.	Tonnage.	Seamen.
1746	1200 to 1500	——	——
1792	3113	185,336	
1799	2183	124,129	18,000
1806	2529	136,166	
1810	1972	100,938	

Baltic.

In 1807, the Danish fleet consisted of 26 sail of the line; 16 frigates; 9 sloops, and 30 gun-vessels.

Swedish Commerce.

The foreign commerce of Sweden is confined to a certain number of ports, which have custom-houses; these are called staple towns; they are Stockholm, Gottenburgh, Warberg, Halmstad, Nordkœping, Landscrona, Carlscrona, Christianstad, Carlshamn, Calmar, Westervic, Uddervalla, Marstrand, Gefle, and Abo and Wasa in Finland, now given up to Russia. The foreign commerce is supposed to be divided among these cities, as follows:

Stockholm $\frac{7}{13}$ths of exports,	and $\frac{1}{2}$ of imports.
Gothinburgh $\frac{2}{13}$ths	$\frac{1}{4}$
The other ports $\frac{4}{13}$ths	$\frac{1}{4}$

Sweden exports to the foreign parts of the Baltic, iron, steel, copper, lime, alum, and herrings, and receives corn, hemp, tallow, and hides. To Holland, she exports iron; and receives spices, tobacco, prepared colours and papers. To England, she exports iron, timber, pitch, tar, potash, and herrings; her imports are lead, tin, leather, bear, butter and cheese; and every kind of manufacture and colonial produce. In France, Spain, and Portugal, the exports are iron, steel, copper and brass, and wines, brandy, fruits; oil and silks are the returns. To Italy and the Levant she exports all her territorial productions; and receives salts, spices, fruits and cotton. There are from four to six ships of 600 to 1000 tons burden in the East India trade. In 1800, she had above 2000 merchant vessels of 20 tons and upwards; but the rupture with England and cession of Finland reduced them, in 1810, to 1500. In 1809, her navy was reduced, in consequence of her wars with Russia, to 13 sail of the line, 9 or 10 frigates, and about 150 vessels of the flotilla.

Prussian Commerce.

The Prussian ports, including Dantzic, export almost the whole of the commercial productions of Poland, consisting of corn, fir planks and rafters, masts, hemp, tar, pitch, potash, hides and tallow, leather, honey and wax; besides Pomeranian oak, brandy, woollens, linens, caviar, and amber. The imports are wines, coffee, sugar, tobacco, spices, salt, iron, copper, Spanish wool, herrings, and flax seed from Livonia and Courland. Towards the close of the last century, the merchant marine of the Prussian ports on the Baltic, consisted of between 900 and 1000 ships. Salted and smoked meat, hides, wool, butter, cheese, corn and fruits, are the exports of that part of Pomerania which belonged to Sweden and Mecklenburgh; the corn of the latter is principally taken off by England; that of Pomerania, as well as the fruits, used to go to Sweden.

Russian Commerce.

The following table exhibits the exports and imports of Russia, so far as her commerce in the Baltic is concerned, in the beginning of this century:

	Exports. Rubles.	Imports.
1802 -	47,000,000	33,000,000
1804 -	45,000,000	27,000,000
1805 -	52,000,000	29,000,000

The commercial marine of Russia is very small; the total number of her merchant-vessels that navigate the Baltic and the Ocean, not exceeding 50; 100 smaller vessels carry on the coasting-trade of the Baltic; and about 100 craft of 20 or 30 tons are employed in loading and discharging the vessels at Cronstadt, that cannot enter the Neva. At the close of the year 1807, the Russian Baltic fleet consisted of 20 sail of the line, 14 frigates, six brigs and cutters, and 19 small craft; and the Baltic flotilla, of 20 gallies, 25 floating-batteries, 81 gunboats, and 16 yauls.

Baltic ‖ Bamboo.

During the year 1815, there passed the Sound, inwards and outwards, in January, 45 ships; in February, 17; in March, 147; in April, 692; in May, 1243; in June, 1104; in July, 1476; in August, 1171; in September, 1251; in October, 783; in November, 542; and in December, 274; making a total, in the course of the year 1815, of 8745.—In the height of the season, not fewer than 100 vessels pass every four-and-twenty hours, for many weeks in succession.

See Thomson's *Travels in Sweden; Tableau de la Mer Baltique*, par Catteau; *Tableau des Etats Danois*, par Catteau; Macpherson's edition of Anderson's *History of Commerce;* Oddy's *European Commerce; Maritime Geography and Statistics*, by Tuckey, Vol. I. (c.)

BAMBOO. Privation of some ordinary substances, which attract little attention from common observers, would materially affect the convenience of entire nations. Few are wont to appreciate the incalculable value of limestone in the quarry, or iron in the pit, or even to form any conjecture of how the arts and manufactures of this country could be carried on without them. In the same manner, the bamboo, a plant of universal use in other regions, scarcely receives the slightest notice, unless when its properties, for which there is no substitute in the use of any other vegetable, are considered in detail. It is to millions in the east what the most useful raw material is to the western world.

Description of the Bamboo.

This plant is generally ranked by botanists in the number of reeds; but some, less sensible of its analogies with them, incline to institute a separate genus for it. In the *Systema Naturæ*, Linnæus describes two species, under the genus *Bambusa*, which is characterized by "scales three, covering the spikelets, which are about five flowered; calyx none; corolla, a two valved glume; style bifid; seed one." Loureiro, who had an opportunity of studying the nature of the bamboo in its own climate, characterizes it as having "flowers with six stamina; panicle diffused, with imbricate spikelets; branches of the culm spiny; calyx one flowered." We shall abstain from discussing the more minute botanical characters, as it is to the real utility of the plant that our attention is to be specifically directed. The bamboo is a native of the warmer climates only, though growing luxuriously without the limits of the torrid zone. It rises to the height of 40, 60, or even 80 feet, with a slender hollow stem, shining as if varnished. Many, however, and probably according to the particular species, are only 12 or 15 feet high; and those which attain the greatest height here mentioned, are rather to be viewed in the same light as the overgrown vegetable productions of our own country. The stem is extremely slender, not exceeding the thickness of five inches in some which are 50 feet high, and in

Bamboo.

others reaching 15 or 18 inches in diameter. The whole is divided into joints or articulations, separated by a short interval, called a knot or internode, and in some there is the distance of several feet between each. Small alternate branches spring from the base to the top, which, together with the narrow pointed leaves issuing from the knots, give the tree an elegant feathered appearance as it waves in the wind.

Varieties.

The rapidity of growth is surprising in the bamboo. It sometimes vegetates three or four inches in a single day. Accurate observers have seen it rise 20 feet, and as thick as a man's wrist, in five or six weeks; and it has been known to reach 30 feet in six months. This enables us to credit the assertions of those naturalists who maintain, that its full dimensions are attained in a year; and that the only subsequent change is greater thickness and induration of the wood. It is always more solid and compact towards the root, and the hollow cells of the stem become wider in proportion as they ascend. In Malabar it is said to bear fruit when 15 years old, and that it then dies. Slenderness is a distinguishing characteristic of the whole plant, and it seems probable that there are several different species which have not yet been recognised by systematic botanists. Soil and climate may have also produced effects which would disappear on uniformity of circumstances. An observer of the bamboos of China, in general, considers that there are ten species or varieties, and an observer of those in Cochin-China admits of eight. The former judges the difference to consist, first, in the size and height, for there is here the greatest disparity in those that are full grown; and it has been supposed that some, if not all species, originally spring of their ultimate diameter, which receives no accession. Secondly, The distance of the knots, or length of joint, which, in certain species of full-grown bamboo, is only four inches, while, in others young and slender, they are nine or ten feet asunder. Thirdly, In the colour of the wood, which is whitish, yellow, brown, pale blue, or speckled. Fourthly, In the size and form of the knots, some swelling out from the stem above and below; some encircling it like a cord; and those of the most singular kind, which do not penetrate within to interrupt the tubular part of the bamboo. Fifthly, By the surface and figure of the internodes being channelled or covered with tubercles; and a kind is said to exist, called the square bamboo. The varnished surface is also of different quality. Sixthly, The substance and thickness of the wood, which, varying without any relation to the dimensions of the plant, afford sufficient characteristics for constituting a species. The wood is either soft and tender, or very hard and of great strength; and the stem is either very thin and hollow, or almost totally filled up and solid, like other trees. But elsewhere, in Bangalore for example, this solidity is not ascribed to the difference of species, but to the tardiness of its growth in stony places. Seventhly, It is said that there are bamboos entirely devoid of branches, however old they may be; while others protrude as they spring from the earth. Eighthly, There is a great difference both in the hue and figure of the leaves, as also in their size; they are bluish, ash-colour, reddish, or mottled. Some are so large as to make very good fans. Ninthly, The roots, though knotty and irregular, are found in one species to penetrate like a large tuft of filaments into the earth. Tenthly, There are certain singularities which distinguish the species of this plant, in excrescences from the knots, which may be ate; a saccharine pith; and wood of a red colour and agreeable odour.

It will easily be observed, that these remarks are too general to warrant the establishment of species from all the bamboos enumerated; but it is not improbable that a plant, so widely diffused, may consist, as before observed, of a greater number than are yet recognised.

The bamboo grows wild in most places of the east, and the warmer parts of the west, and is resorted to as occasion requires. Where the country is principally dependent on its use, it is cultivated in regular plantations; and, in more ungenial climates, preserved by the curious in greenhouses. Its culture is different, according to soil and climate; but apparently it succeeds best in low sheltered grounds, with rich, soft, spongy earth. Contact of the root with water is reputed to be immediately destructive, and too much humidity occasions gradual decay. This plant is propagated by shoots deposited in pits at the close of autumn or commencement of winter, eighteen inches or two feet deep; and if it be designed to obtain bamboos of considerable size, the scyons are cut over as they spring up. Some scrupulous cultivators among the easterns take care to preserve the plant exactly in the same position, with respect to the cardinal points, as that in which it originated. The greater the number in a plantation, the more the chance of success, as they shelter each other in their progress. Their subsequent treatment depends entirely on the uses to which they are to be converted, whether to profit or pleasure; much care being bestowed on those designed for beauty or ornament only. They are propped up with rods of a proper height, by which they are trained and supported; and, if complete plants, cut over in order to obtain suitable shoots, which are chiefly sought after; besides, this operation makes the root strike out and take a secure hold of the ground. In a rainy season, it is always necessary to surround the plantation with a ditch, in order to drain off the superabundant humidity which would otherwise be prejudicial. Various expedients are followed to obtain good bamboos, of which one of the most usual is to take a vigorous root, with firm wood, and transplant it, leaving only four or five inches above the joint next the ground. The cavity is then filled with a mixture of horse-litter and sulphur. According to the vigour of the root, the shoots will be more numerous; but they are destroyed at an early stage during three successive years; and those springing in the fourth will resemble the parent tree. It is affirmed that no culture can obtain any thing of larger size.

Various important Uses.

Scarcely has this plant been put in the ground before its utility becomes conspicuous. The soft and succulent shoots, when just beginning to spring, or only some inches long, are cut over and served up to table, like asparagus. Like this vegetable also, they are earthed over to keep them longer fit for con-

Bamboo. sumpt; and they afford a supply in succession during the whole year, though more abundantly in autumn. They are also salted and ate with rice, or prepared after different other fashions. As the plant grows older, a kind of fluid of grateful taste and odour is secreted in the hollow joints, affording an agreeable beverage, and in sufficient quantity to satisfy several persons. If allowed to remain in the tree, a concrete substance, highly valued for its medicinal properties, called *Tabaxir* or *Tabascheer*, is produced from it. The presence of the fluid is ascertained by agitating the bamboo; after some time its quantity gradually diminishes, and then the stem is opened to reach the Tabascheer. This substance, participating in nothing of a vegetable nature, has been supposed to be nearly allied to siliceous earths; it resists the impression of all acids, is indestructible by fire, and with alkalies forms a transparent glass. Notwithstanding its repute in the east, we are not aware that it has yet been received into the European materia medica. Besides the Tabascheer, many parts of the bamboo are said to be endowed with medicinal properties; a decoction of the leaves is recommended for coughs and sore-throat; the bark for fever and vomiting; the buds as a diuretic; and a compound of the root with tobacco-leaves, betel-nut, and oil, is believed to form an efficacious ointment. But setting aside its medical properties, it is highly valuable as an article of food, for many of the poorer classes in the most populous countries subsist on it in times of scarcity. The seed which it produces is recorded, in Chinese history, to have preserved the lives of thousands; the Hindoos eat it mixed with honey as a delicacy, equal quantities of each being put into a hollow joint, coated externally with clay, and thus roasted over a fire.

From the copious draught which a joint of the bamboo naturally yields, mankind are taught its use as a vessel for carrying water, and in some places no other bucket is employed. The Eastern nations build their houses solely of the wood without any auxiliary substance; if entire, it forms posts or columns; split up, it serves for floors or rafters; or interwoven in lattice-work, it is employed for the sides of rooms, admitting light and air. The roof is sometimes of bamboo solely, for which two species growing in Laos, an Asiatic country, are described to be specially adapted; and when split, which is accomplished with the greatest ease, it can be formed into lath or planks. It is employed in shipping of all kinds, and as houses are constructed entirely of it, so are complete vessels framed out of it likewise, and fitted for sea. The hull is obtained from the stem; and some of the strongest plants are selected for masts of boats of moderate size. In Bengal, a boat of four or five tons may be furnished with both mast and yard from the same bamboo, at the cost of threepence; and the masts of larger vessels are sometimes formed by the union of several bamboos built up and joined together. Those of considerable dimensions are used in the higher yards of ships of four or five hundred tons, for which service they are well adapted by their great strength and lightness.

The bamboo is employed in the construction of all agricultural and domestic implements; and in all materials and implements required in fishery, hooks and nets excepted. In Tibet the strongest bows are made of it, by the union of two pieces with many bands; and in the same country also, it is employed, as we use leaden pipes, in transmitting water, for the distance of several miles, to reservoirs or gardens. The species from which these pipes are constructed is said to grow in the mountains; and from other light and slender stalks, the inhabitants obtain shafts for their arrows. In the south-west of Asia, there is a certain species of equally slender growth, from which writing-pens or reeds are made.

Bamboo ‖ Banda Islands.

From the extreme flexibility of this substance, and also its divisibility, for it splits like whalebone from top to bottom, it can be reduced to the smallest dimensions, and bent into every shape. It is woven into baskets, cages, hats, or various ornamental articles. By a particular process in bruising and steeping the wood or bark, a paste is procured that is made into paper. In short, from its very origin until its decay, it never ceases to produce something beneficial. It has justly been observed, "All that composes a bamboo is profitable, of whatever species it may be. The artists of China have each made their choice, and in the works they produce, show the advantage they have derived from it. Its uses are so numerous, so various, and so beneficial, that it is impossible to conceive how China could now dispense with this precious reed. It is no exaggeration to affirm, that the mines of this vast empire are of less importance to it than possession of the bamboo."

It has been proposed to naturalize the bamboo in France. Perhaps were the naturalization of plants and animals attempted by slow and regular gradation, instead of great and sudden transition, experiments might be more successful than former practice would authorize us to conclude. Probably it would require the renewal of several successive generations, each advanced into a different climate not remote from the abode of the one which preceded it, before naturalization could be completely effected. Some European climates might not prove noxious to the bamboo; but the same rapidity of vegetation, the same natural qualities, could not be expected, or only in an inferior degree, even in the most favourable situation, and consequently its utility would be infinitely diminished. (s.)

BANDA ISLANDS. These Islands, situate 130 miles to the south-east of Amboyna, are ten in number, viz. Banda Neira, Gonong Apee, Banda Lantoir, Pulo Ay, or Way, Pulo Rondo, or Pulo Roon, Rosyngen, Pulo Pisang, Craka, Capella, and Sonangy.

General Description and History of these Islands.

Of these, Banda Neira is the seat of the supreme government, and it is secured by one principal fortification, situate on the south side of the Island, consisting of a small square fort, having a wet ditch, with a horn-work towards the sea. This fortification, which is called Fort Napau, forms the chief defence of the Banda Islands. The troops are quartered, and the public granaries are kept in this fort; but the storehouses for the nutmegs and mace are on the outside, as well as the government-house.

Banda Islands.

Above Fort Napau, on a neighbouring eminence, stands the castle of Belgica, an old pentagon, with round towers at the angles. It is surrounded with a wall, secured by small bastions, but has no ditch, and is said to have been built by the Portuguese.

Banda Lantoir, or Great Banda, is to the northward of Banda Neira. It is defended by a considerable fort, which commands the harbour of Lantore, and is called Fort Hollandia. At first view, the situation of this fort appears preferable to Banda Neira for the residence of government, not only on account of its strong and commanding situation, but because the Island is the largest, as well as the richest, in the produce of spices. Its unhealthiness has been found, however, to be a sufficient objection. The water is said to be bad, and the vapour which sometimes descends from the volcanic mountain of the neighbouring Island Gonong Api, is represented as particularly noxious. Such fatal effects were produced by these causes, that when the Wirtemberg Company formerly garrisoned the Island, out of a hundred men, eight died, and forty fell sick, in the course of two months. The numbers of decayed houses, also, which are seen in different parts of the Island, show that the experiment of a settlement has been already tried, and has not been found to answer. This Island appears very high from the sea; its sides are steep, and from the top of them there is a sort of table land, which extends nearly from one end of the Island to the other.

Gonong Apee is to the northward of Banda Neira, and derives its name from a large volcano, about 2000 feet above the level of the sea, which constantly emits smoke, and sometimes cinders and ashes, accompanied with a crackling noise. On the south side of this Island are two forts, originally intended to defend the west channel of Lantore harbour; but owing to an eruption of the volcano in 1778, at the same time that a dreadful hurricane laid waste the Island, the lava flowed down in such quantities as to form a considerable promontory between these batteries and the channel they were intended to defend, so that they are now in a great measure useless. This Island is generally unproductive, its surface being covered with a quantity of sulphur and chalk. There is no vegetation whatever on upwards of one-third of the eminence on which the volcano is situate. Towards the sea, the descent is exceedingly steep; but towards the harbour, the declivity slopes gradually to the water, on the side of which are some plantations, and a few straggling houses.

Pulo Way is about nine miles to the westward of Gonong Apee, and is defended by a strong fort. It is esteemed the most healthy of the whole group, and produces abundance of nutmegs, of a kind superior in quality to those of the other Islands. Pulo Rondo, or Pulo Roon, is about four miles further in rather a more northerly direction. On this Island the English had a factory, from which they were expelled by the Dutch, about the period of the massacre of Amboyna; and the Island having been since abandoned, has become a wilderness. Rosyngen is about seven miles to the south-east of Lantore. It produces nutmegs, mace, yams, and subsistence for a few cattle. The convicts of Amboyna were formerly kept on this Island, and were compelled to cultivate the land for the use of the supreme government. Pulo Pisang is about two miles north-east from Banda Neira, and yields some fine fruits, as well as nutmegs and mace. The other three Islands are uninhabited, being little more than barren rocks.

The Banda Islands were discovered in the year 1511 by the Portuguese, who immediately took possession of them in the name of their sovereign. About the year 1603, they were expelled by the Dutch. In 1608, the English, with the permission of the king, built a factory-house on Pulo Way, which the Dutch demolished as soon as the ship which brought out the factors returned to England. The natives of Banda, notwithstanding the opposition of the Dutch, assisted the English in forming a new colony, and shortly afterwards they, along with the natives of Lantore, made a formal resignation of their respective Islands to the new settlers. In 1620 Pulo Roon and Pulo Way were added to the English dominions, and those cessions were confirmed by a treaty concluded between the English and the Dutch. But, in defiance of this treaty, the latter determined on the expulsion of their rivals from those Islands, in the possession of which they appeared to be gradually establishing themselves. They accordingly attacked them with a strong force, seized their factories, magazines, and shipping, and after stripping the factors naked, first whipped and then loaded them with irons. Some notion may be formed of the trade, then in its infancy, by the quantity of spices seized here, which amounted to 23,000 lbs. of mace, and 150,000 lbs. of nutmegs. In 1654, the Dutch were compelled, by the firmness of Cromwell, to restore the Island of Pulo Roon, and to make satisfaction for the massacre of Amboyna. But the English settlers not being adequately supported from home, were unable to resist the power of their rivals, and the Island was retaken by the Dutch in 1664. They retained undisturbed possession of their conquests in this quarter of the globe until the year 1796, when the Banda Islands, along with all the other Dutch colonies, were conquered by the British. They were restored by the treaty of Amiens, in the year 1800, but were again captured, and have been again restored, by the treaty of Paris, concluded in the year 1814.

In the space between Banda Lantoir and the Islands of Banda Neira and Gonong Apee, there is a very good harbour formed with entrances both from the east and west, which enable vessels to enter it from either of the monsoons. These channels are well defended with several batteries, particularly the western one, which is very narrow. Between Gonong Apee and Banda Neira, there is a third channel into this harbour from the north; but it is navigable only for small vessels.

Culture, Varieties, and Commerce of the Nutmeg.

The great articles of commerce in these Islands are nutmegs and mace, which are engrossed at a fixed price, for the benefit of the Dutch East India Company, and the laws and regulations generally established, are calculated to support and promote this monopoly, rather than the happiness of the people, or the improvement of the country. With this view, the cultivation of the nutmeg is only allowed in the

Islands of Banda Neira, Gonong Ap, Banda Lantoir, and Pula Ay. In all the other Islands the tree has been carefully extirpated, because, being at a distance from the seat of government, they were supposed to afford better opportunities for smuggling. In the Islands which are appropriated to the cultivation of the nutmeg, they neither feed cattle nor produce grain sufficient for the maintenance of the inhabitants, and they are on this account dependent on Batavia for annual supplies of rice, and other articles of provision. In consequence of the low state of agriculture occasioned by this policy, the inhabitants are few, and the number of hands that would be necessary to bring the nutmeg plantations into the highest state of cultivation, cannot be procured. This scarcity of hands renders it necessary to recruit the declining population by the importation of slaves. It would appear, also, that the inhabitants suffer severely when the supplies of provisions on which they depend from abroad happen to be interrupted, and that, in these circumstances, their wants subject them to the greatest oppressions. About fifteen months before these Islands were last conquered by the British, some reforms in the system of administration were carried into effect by a new governor who had been appointed for that purpose. But before this period most of the planters were in great distress, having been charged with very heavy debts, incurred on account of loans in rice and money, made at different periods by the former governors, and this circumstance, joined to the great loss which they sustained by the dreadful hurricane of 1778, entirely ruined their private fortunes as well as their plantations. While they were in these distressed circumstances, the Dutch government, with an unfeeling avarice, aggravated their misery by compelling them to deliver their nutmegs, at the reduced price of three farthings *per* pound, and the mace at a still lower rate. Under this accumulated distress, the spirit which had animated their fathers in the days of their independence seemed once again to revive, and they remonstrated in bold and determined language. They claimed the lands as their own prescriptive inheritance, which they undoubtedly were, and actually proceeded to portion out their respective properties to each other. The Dutch, though they were touched by no feeling for the deplorable situation to which they had reduced the country, were nevertheless alarmed when they saw their discontented subjects determined to resist, and it was thought advisable to adopt a more just and conciliatory conduct. With this view, the accumulated arrear of debt claimed by the company from the planters, and which most of them were unable to pay, was cancelled. Several judicious regulations were also adopted regarding the management of slaves, and the price at which the government received the spices of the planters, were at the same time increased from the low rate to which it had been reduced to seven and a half stivers per lib. for mace, and to two and a half stivers for nutmegs, with a deduction of 17 *per cent.* in favour of the company and their servants.

In return for these concessions, it would appear, that the company, after having pacified their subjects, seized their lands, and in this manner they continued to practise the same oppression as before, though the mode of it was somewhat different. The planters in general, if they had been once freed from the enormous debt claimed by government, would, from the produce of their plantations, have speedily discharged all other claims, and they considered it hard, therefore, that, under colour of remitting this debt, they should be deprived of their respective properties, to which prescription gave them an undoubted right.

The nutmeg-tree is a native of several of the Islands to the eastward; but it has been in a great measure extirpated from them all except Banda. It begins to bear fruit at ten years growth, the fruit improving in quality, and increasing in quantity, until the tree has attained the age of an hundred years. In its appearance it is handsome and spreading, the bark is smooth and of a brownish grey colour. The leaves resemble those of the laurel, and afford, when bruised, a grateful aromatic scent. When the tree first begins to produce fruit, little yellowish buds make their appearance, out of which small white flowers are blown, two or three hanging upon slender peduncles. In the centre of the flower is an oblong reddish knob, from which the fruit is produced, though no more than one blossom out of three commonly ripens to a nutmeg. It is eight or nine months before the fruit arrives at maturity; but blossoms and ripe fruit are found together on the same tree, and the nutmegs are generally gathered three times in a year. The nutmeg, when ripe on the tree, has both a very curious and beautiful appearance. It is almost the size of an apricot, and nearly of the same colour, with the same kind of hollow mark all round it. In shape it is somewhat like a pear. When perfectly ripe, the rind over the mark, which is nearly half an inch thick, and of a whitish colour, opens, and displays the nutmeg in its black and shining shell, encircled by a net-work of scarlet mace. The shell in which the nutmeg is inclosed is about as thick as that of a filbert, and very hard. In preparing the fruit for use, the mace is first stript off and kept in baskets to dry in the sun, and the nutmeg in its shell is placed before a slow fire to dry in five different houses made of split bamboos, fitted up for the purpose. In each of these houses it remains a week, till it is heard to shake within the shell, which is then easily broken. The nutmegs thus prepared are sorted into separate parcels. Each sort is put up by itself into baskets, and soaked three times in tubs of sea water and lime; after which they are put into distinct closets, where they are left for six weeks to sweat, that the lime, by closing the pores of the nutmeg, may prevent its strength from evaporating. The lime is necessary to preserve the fruit from worms and other insects, and it requires much experience, as well as a considerable degree of judgment, to ascertain the precise time that the fruit should be suffered to remain in the lime; for, if it be taken out too soon, it is worm-eaten, and if it is left to remain too long in the lime, it is burnt up and rendered useless.

The nutmeg is distinguished into three sorts, namely, the male or barren nutmeg, the royal nutmeg, and the queen nutmeg. The two last species are distinguished by the different sorts of fruit which

Banda Islands.

they produce, that of the royal nutmeg being thicker, longer, and more pointed. The green shell is also thicker. It does not ripen so fast; and after opening, it preserves its freshness eight or nine days. The mace is more substantial, and three times as long as that of the queen nutmeg, and its stripes or thongs, of which there are from 15 to 17 principal ones, are of a livelier red; they are also broader, longer, and thicker, and not only embrace the nut through its whole length, but pass it, and cross under it as if to prevent it from falling. The royal nutmeg is generally from 15 to 17 lines long, and thick in proportion. It remains on the tree a long time after the opening of the green shell, and gives birth to an insect in the shell, which feeds upon it, and destroys it. The queen nutmeg produces much smaller nuts, only nine or ten lines long, not so thick by a third, and well marked by a longitudinal groove on one side. They are round, and the green shell is not so thick. The mace, which is composed of nine or ten principal stripes, grows only half down the nut, thus leaving it at liberty to detach itself, and to escape from the insect formed in the shell. In two or three days, also the green shell, losing its freshness, soon falls away from the nut.

Nutmegs should be chosen large, round, heavy, and firm, of a lightish grey colour on the outside, and the inside finely marbled, of a strong fragrant smell, warm aromatic taste, and a fat oily body. The oblong kind, and smaller ones, should be rejected. The real quantity of nutmegs produced has never been exactly ascertained. The largest quantity sold by the Dutch East India Company at one time was 280,694 libs. in the year 1737. In 1756, there were sold 241,427 libs. and in 1778, 264,189 libs. The average quantity annually sold in Europe has been stated at 250,000 libs. exclusive of about 100,000 libs. disposed of in the East Indies. The produce, however, has since greatly declined, which may be imputed to various causes. In the year 1778, the nutmeg plantations were laid waste by a tremendous hurricane, and this calamity was succeeded by oppressions on the part of the government, and by disturbances among the people; agriculture and industry were in consequence neglected, and the annual produce of spices of all sorts, which amounted to 600,000 libs. was suddenly reduced to 50,000 libs. For seven years previous to the commencement of the war with France in 1793, the average quantity of nutmegs sold in Holland amounted only to 22,459 libs. and that of mace to 7504 libs. When Banda was taken by the English in 1796, the quantity of spices in the warehouses amounted to 84,777 libs. of nutmegs, and to 19,587 libs. of mace. In the several years of 1803, 1804, and 1805, when the Banda Islands were in possession of Britain, there were imported of nutmegs 104,094, 117,936, and 35,851 libs., which were sold for L. 46,233, L. 54,733, and L. 23,742. The quantity retained for home consumption amounted on an average to 39,071 libs. *per annum*, and the revenue which they yielded to L. 7879. The permanent duty levied on nutmegs in this country is 3s. 6d. *per* lib.; and the war duty 1s. 2d., making together 4s. 8d. *per* lib.

Of mace, the quantity consumed in Britain has decreased since the establishment of the East India Company. In the year 1615, the consumption amounted to 15,000 libs. In 1803, when the Islands were in possession of Britain, the whole quantity only amounted to 24,234 libs., and the sole value was L. 53,356. The quantity retained for home consumption was, on an average, from 1804 to 1809 inclusive, 5400 libs. *per annum*. The duty on mace imported is 7s. 8d. *per* lib. Mace should be chosen fresh, rough, oleaginous, of a fragrant smell, a bright reddish yellow, and the smaller pieces are esteemed the best. See Milburn's *Oriental Commerce*, and the *Asiatic Annual Register*. (o.)

Banda Islands || Bandello.

BANDELLO, a celebrated Italian novelist, was born at Castelnuovo, in the neighbourhood of Tortona, about the year 1480. In his youth, he studied both at Rome and at Paris; and his education being completed, he went to reside at Mantua. There he remained for several years much esteemed by Pirro Gonzaga, who entrusted him with the education of his daughter, the celebrated Lucrezia Gonzaga. The incidents in the lives of literary men, who flourished in Italy during the sixteenth and seventeenth centuries, have a strong similarity to each other. Like most of his literary contemporaries, Bandello passed from one petty court to another, and was frequently employed in political missions by the patron whom he served at the time. At this period, the small states of Italy were divided between the French and Spanish interests. Bandello had chiefly attached himself to those princes of Lombardy who favoured the French party; and, in consequence, when the decisive battle of Pavia put the Spaniards in possession of Milan, where Bandello at that time resided, his paternal mansion was burned, and the property of his family confiscated. He fled in disguise from Milan, and after wandering from town to town, he placed himself under the protection of Cesâr Fregoso, a celebrated captain of that age, who had recently quitted the Venetian for the French service. With this general Bandello resided in Piedmont, till a truce was concluded, when he accompanied his patron to France. After the death of Cesar he continued to live with his widow and family at Agen, to the Bishoprick of which he was raised by Francis I. in 1550, and continued to reside in the vicinity of that town till his death, which happened about 1562.

During his residence at Agen, Bandello revised and added to his Novels, which he had written in Italy during his youth, and which some of his friends had recovered from the hands of the Spanish soldiers, who burned his house at Milan. His *Tales* were first published at Lucca in 1554, 4to. In the complete editions of Bandello, the work is divided into four parts—the 1st, 2d, and 3d parts, containing 59 stories, and the 4th comprehending 28. The whole are dedicated to Ippolita Sforza, though she died before their publication, because it was at her desire that the work was originally undertaken. Besides this general dedication, each novel is addressed to some *Valoroso Signore*, or *Chiarissiona Signora*, and in these introductions, the novelist generally explains how he came to a knowledge of the event he is about to relate. He usually declares that he heard it told in company,—details the conversation by

which it was introduced,—and pretends to report it, as far as his memory serves, in the exact words of his authority.

Bandello is chiefly indebted for his celebrity to these Novels, which belong to a class of composition that enjoyed for many centuries the utmost popularity in Italy. The tales of the French Trouveurs, having passed into Italy towards the close of the thirteenth century, were first imitated in the *Cento Novelle Antiche;* which also contains stories formed from episodes in the romances of chivalry, the ancient chronicles of Italy, and jests or repartees current by oral tradition. Boccaccio, whose *Decameron* appeared shortly after, identified this species of composition with the history of Italian literature, and the progress of the Italian language. That celebrated writer was followed by Sacchetti, Ser Giovanni, Centhio, and a numerous tribe of imitators, of whom Bandello is by much the best known, and most celebrated, at least in this country. His popularity, however, has not been so great in Italy, which may probably be attributed to the negligence and impurity of his style; a defect of which the author himself appears to have been conscious, as he repeatedly apologizes for his defects in elegance of diction. *Io non son Toscano, nè bene intendo la proprieta di quella lingua; anzi mi confesso Lombardo.* Napioni, in his eulogy of Bandello, confesses that he is not remarkable for that harmony of periods, and delightful *naïveté* of expression, for which Boccaccio and others of his predecessors were so distinguished; but he adds, that none of the Italian novelists are so interesting for the developement and illustration of minute historical facts, which would in vain be sought for in the histories of the revolutions of the Italian States. Some of the novels of Bandello, however, it must be admitted, are little edifying; and it is curious, that one of his stories, which is perhaps the most obscene in the whole series of Italian novels, should be declared, in the introduction, to have been related by the celebrated Navagero, to the Princess of Mantua and Duchess of Urbino. Besides, notwithstanding the repeated assertions of Bandello, that all his stories have some foundation in fact, and the light which his eulogists suppose that they throw on the history of the Italian Republics, it cannot be denied, that the greater proportion of them are derived from the Fablieux of the French Trouveurs, and the works of preceding Italian novelists, with an alteration of the names, and some slight variations in the incidents. But while Bandello has thus copied largely from preceding fablers, none of their works have suggested more to others, or are more curious for illustrating the genealogy of fiction, and the transmission of fabulous incident, from the novelist to the dramatic poet. Many of the tales of Bandello were translated by Belleforest in his *Histoires Tragiques*, whence they found their way into Paynter's *Palace of Pleasure*, and other works of a similar description which appeared in England, during the reign of Queen Elizabeth. In this manner they furnished the plots of many tragedies and comedies, to the most numerous and noble race of the English dramatic poets. That part of Shakespeare's *Much Ado about Nothing*, which relates to Don John, Claudio, and Hero, is taken, with little variation in the incidents, from the twenty-second tale of the first part of Bandello; and *Twelfth Night* is borrowed from the thirty-sixth of the second part. Massinger has been indebted for his *Picture*, which is, perhaps, the most agreeable and fanciful of his dramas, to the twenty-first of the first part; while Beaumont and Fletcher have derived from the same source their comedy of the *Maid in the Mill*, and the *Triumph of Death*, which is the third of their "Four Plays in One." The thirty-fifth of the second part of Bandello is the same story as the plot of Horace Walpole's *Mysterious Mother*, and the thirtieth tale of the Queen of Navarre. As the works of Bandello and the Queen of Navarre were printed nearly at the same period, it is not probable that they copied from each other, and it may be presumed, that some current tradition furnished both with the horrible incident they report. Mr Walpole, however, disclaims having had any knowledge of the tale of the Queen of Navarre, or Bandello, at the time he wrote this drama. Its plot, he says, was suggested by a story he heard when very young, of a lady, who, under uncommon agonies of mind, had waited on Archbishop Tillotson, and besought his counsel in what manner she should act under the fatal circumstances that had occurred.

Besides his *Tales*, Bandello is author of a poem in eleven cantos, which was his first work, and is now very scarce, entitled, *Delle Lodi, della Signora Lucrezia Gonzaga*, printed at Agen, 1545, in 8vo. He also wrote a complimentary poem, in three cantos, on the birth of a son of his patron, Cesar Fregoso. Both these productions are written without taste or spirit; but it is said, that some good verses, composed by Bandello, on different subjects, are still preserved in manuscript in the library of the Academy of Turin. (M.)

BANDINI (ANGELO MARIA), a learned Italian, was born at Florence on the 25th September 1726. Having been left an orphan in his infancy, he was supported by his uncle, Joseph Bandini, a lawyer of some note. He was educated among the Jesuits, and discovered an early passion for the study of antiquities. A desire which he also manifested to distinguish himself as a poet, was fortunately checked by the ill success of his first attempt; and, from that period, he devoted himself principally to literary history and archaiological science. The celebrated Dr Lami, with whom he had the good fortune to contract a friendship, assisted him with his counsels, and encouraged him to persevere in that path, to which his genius seems to have directed him.

In the year 1747, Bandini undertook a journey to Vienna, in company with the Bishop of Volterra, to whom he acted in the capacity of secretary. He was introduced to the Emperor, and took the opportunity of dedicating to that monarch his *Specimen Litteraturæ Florentinæ*, which was then printing at Florence. The following year he returned by the way of Venice, Padua, Ferrara, and Bologna, and united himself in friendship with the learned men in all these cities. Having resided sometime at Florence, he repaired to Rome, and entered into orders,

Bandini. passing the whole of his time in the library of the Vatican and in those of the Cardinals Passionei and Corsini. At that time, the famous obelisk of Augustus was dug out of the ruins of the *Campus Martius*. Bandini, by the order of Benedict XIV., undertook to describe and explain this curious monument; but finding that the air of Rome was injurious to his health, he returned to Florence. In 1750, he was selected by Alexander Marucelli to take charge of the valuable library, which his uncle, the Abbé Francis Marucelli, had left, and which, according to the will of the founder, was to be open to the public. But he had scarcely entered upon the duties of this charge when the proprietor died, after bequeathing all his effects to the library, and appointing the Abbé Bandini perpetual librarian and his testamentary executor. It required two years to liquidate the succession, and to form the complete catalogue of this vast library, which was at length opened to the public in the year 1752. In 1756, he was preferred by the Emperor to a prebend at Florence, and appointed principal librarian to the Laurentian library. During forty-four years he continued to discharge the duties of this situation, and died in 1800, generally esteemed and regretted. On his deathbed he founded a public school, and bequeathed the remainder of his fortune to other charitable purposes.

The first work by which Bandini became known as a man of letters was his *Dissertatio de veterum Saltationibus*, which he wrote at the age of twenty-two, and which was inserted by his learned friend Lami in the fifth volume of the works of Meursius, published in 1745. The most remarkable of his other works are, 1. *Specimen litteraturæ Florentinæ seculi XV.* &c. 2 vols. 8vo. 2. *De Obelisco Augusti Cæsaris, e Campi Martii nuderibus nuper eruto*, 1750, fol. 3. *Collectio veterum aliquot Monumentorum ad historiam, præcipue litterariam pertinentium.* 1752, 8vo. 4. *Elogio dell' ab. Francisco Marucelli fondatore della publica libreria Marucelliana.* 1754, 4to. 5. *Vita e letere di Amerigo Vespucci.* 1745, 4to. 6. *De vita et scriptis Joan. Bapt. Donii Patricii Florentini, libri V. adnotationibus illustrati; accidit ejusdem Donii litterarium commercium nunc primum in lucem editum.* 1755, fol. 7. *Vita di Filippo Strozzi.* 1756, 4to. 8. *Vita del cardin. Niccolo da Prato.* Eod. an. 4to. 9. From 1763 to 1766, he employed himself in publishing successively the works of some of the minor Greek poets, which he enriched with notes and various readings. These were Callimachus; the two poems of Nicander on poisons and antidotes; the *Phenomena* of Aratus; the poems of Musæus; those of Colluthus on the rape of Helen, and Tryphiodorus on the taking of Troy; Theognis, Phocylides, and the golden verses of Pythagoras. The Greek text of these poems was carefully collated with the best manuscripts; and there were added translations, in Italian verse, by Ant. Mar. Salvini. 10. *Catalogus codicum manuscriptorum Græcorum, Latinorum, et Italorum, bibliothecæ Laurentianæ.* 1764-78, 8 vols. fol. 11. *Bibliotheca Leopoldina Laurentiana, sive Catalogus Manuscriptorum, qui jussu Petri Leopoldi in Laurentianum translati sunt.* 1791-93, 3 vols. fol. 12. *De Florentini Juntarum Typographia, ejus qui censoribus.* 1791, 2 parts, 8vo. See *Biographie Universelle*, Tom. III. (H.)

Banffshire. Situation and Extent. BANFFSHIRE, a county in the north of Scotland, having the Murray Firth on the north, Aberdeenshire on the east and south, and the county of Moray on the west, is situate in the 58th degree of north latitude, and contains 647 square miles, or, without including a small space covered by water, 412,800 English acres. Surface. Along the coast, for about 30 miles, the soil consists chiefly of sand and loam, and is in many instances well cultivated; but, with the exception of this tract, Banffshire is a hilly, and, towards the south, a mountainous district, though many fertile valleys are interspersed; and there is much valuable grazing land, well sheltered with natural wood, on the banks of its streams, and in its romantic glens. Rivers. The Spey, one of the most considerable rivers in Scotland, which flows on its western boundary, and the Deveron on its eastern, to both of which a number of rivulets are tributary, yield a considerable revenue from their salmon-fishings,—the former, according to the agricultural survey in 1812, upwards of L. 6000, and the latter about L. 2000 yearly. Seats. In the lower part of the country, towards the coast, there are several magnificent buildings, of which Duff House, the principal seat of the family of Fife, Cullen House, the seat of the Earl of Findlater and Seafield, and Gordon Castle, the most princely mansion in the north of Scotland, are the most conspicuous. Plantations. Around these, and a great number of gentlemen's seats in the interior, the plantations are extensive and ornamental; but the extent and the value of the natural woods is inconsiderable.

Minerals. Calcareous substances in the form of marble, limestone, and marl, abound, yet, owing to the want of coals, the greater part of the lime used on the lands near the coast is brought from Sunderland. The other minerals most worthy of notice are freestone, granite, slate, brick-clay, to which must be added the rock-crystals and topazes, found on the mountain of Cairngorum, and other parts of that elevated range which forms the southern and western boundaries of Banffshire. In summer 1811, L. 2000 worth of these stones were found; and in some instances to the value of L. 200 in one day. Cudbear. *Cudbear* or *cup-moss*, though certainly a vegetable substance, may be mentioned along with minerals, from its growing only in rocky mountainous situations. Its use in dyeing purple, after undergoing a simple preparation, is said to have been discovered by Mr Gordon, a gentleman of the parish of Kirkmichael in this county, before the year 1755. In 1808 and 1809 about L. 500 worth of it, gathered on the mountains of Banffshire, and those adjoining in Aberdeenshire, was purchased for the manufactures of Glasgow.

Agriculture. Neither the climate nor the soil of this county, except along the coast, is favourable to extensive aration; the subsoil of the higher grounds being in general retentive of moisture, and grain very late in ripening. Only about a fourth part of its contents is considered to be at all fit for tillage. Almost all the crops usually cultivated in Scotland have, however, gained a firm footing here, though oats occupy by far the greatest proportion of the arable surface. In this, as in the other northern counties, the chief

anffshire.

dependence of the husbandman is on his live stock; and there being comparatively few sheep, the tenantry look to their cattle as the great fund for paying rents and all other charges.

Farms are generally so small as scarcely to deserve the name, most of the land being parcelled out into holdings of less than 30 acres; and the management is but too often incorrect and unproductive. For what improvements have been made in its agriculture, this district is much indebted to one of the Earls of Findlater, who, so early as 1754, not only introduced and exhibited on some of his own farms the most approved practices then known in England, but held out liberal encouragement to his tenants to follow his example. The valued rent is L. 79,200 Scots; and in 1811, according to the assessment to the Property Tax, the real gross rent of the lands was L. 79,396, 3s. 4d., and of the houses L. 5514, 2s. Sterling. The valuation of estates held under entail is more than a half of the whole.

lued and eal Rent.

ichenhal- Work.

The mud buildings, common in some of the northern counties, called *Auchenhalrig work*, from a place of that name in Banffshire, have been found a cheap, and by no means a bad substitute for stone and lime walls in farm offices. About 30 carts of stones, round, or rather small, 10 carts of clay or mud, to which a certain proportion of sand is added, and 24 stone of straw, make a rood of 36 square yards. Several houses built of these materials have stood upwards of a hundred years.

nufac- es.

There is scarcely any thing deserving the name of manufactures in this county. The linen, and more lately the cotton branches, employed a number of hands, but both have declined of late. Coarse woollen stuffs are made in private families for home consumption; and tan-works, breweries, rope-works, &c. have been established on a small scale. Its commerce by sea is equally inconsiderable. At the ports of Banff, Macduff, Portsoy, and Gardenstown, a few vessels carry on a little trade, chiefly coastwise, importing coals, iron, timber, and other necessary articles; and exporting salmon and other fish, butter, and a little grain. But the cattle driven to the southern markets make the principal returns. The salmon-fishings have been already noticed, and there are 10 fishing villages, which, besides yawls, employ from 50 to 60 boats in the white fishery. Herrings have lately appeared on this coast.

Banffshire.

Commerce.

Fishing Villages.

Antiquities.

Several remains of antiquity are pointed out in different parts of Banffshire, of which the churches of Mortlach in the mountains, and Gamay on the shore, are perhaps the most remarkable; exhibiting the savage triumphs of our ancestors over the invading Danes 700 years ago, in their sculls built into the solid walls. Ruins of castles and traces of encampments are frequent; but scarcely any of those circles of stone are to be seen, which are supposed to belong to a much more remote age.

Population.

The population, as taken under the acts 1800 and 1811, is given in the table below; but it appears that, in some instances, the population of parishes, part of which lie in other counties, is included in the returns for these counties.

BANKING.

In the *Encyclopædia* will be found some explanation of the nature and origin of banking; and it now remains to describe the improvements which have been subsequently introduced into this important art of money-dealing, and to give some account also of the principal banks, which, in the progress of commerce and of wealth, have been established in this, and in other countries.

Purpose for which Banks were originally established.

The chief purpose of the different banks which were established throughout Europe during the fifteenth and sixteenth centuries, such as the banks of Venice, Genoa, Amsterdam, Hamburgh, and Nuremberg, was to provide, for the convenience of commerce, a currency of a determinate and invariable standard. Before this period, the currency of those places was lost amid an inundation of the light and debased coins of every adjacent state; and the business of commercial exchange was in this manner obstructed by the want of some certain measure of value. By the establishment of banks of deposit, as they are generally called, which paid all demands on them in money of a known weight and fineness; and by ordaining, at the same time, that all payments above a certain sum should be made in bank money, the greatest possible degree of certainty was given to the value of the currency, while, by adopting the method of paying large sums, by means of a simple transfer from one name to another in the books of the bank, great facility and dispatch were obviously given to all cash transactions. Nor were those advantages confined to the particular places in which banks were established. It was soon found, that the same improvement which was so useful in the domestic transactions of a community could be employed with even greater advantages in simplifying the cash transactions of distant places. The inconveniences to which merchants residing in the same place must have been exposed in making payments to each other, previous to the establishment of banks, would necessarily consist in the want of some fixed and invariable measure of value; in the counting, weighing, and useless transportation of large sums from one hand to another; and in the frauds and mistakes which would frequently occur in these cumbersome transactions. But in the commercial intercourse of distant places, all those disadvantages would be greatly aggravated; there would be more scope for frauds and mistakes; they would be less easily corrected; and, without some system of money-dealing, the commerce of distant places must be limited to mere barter, or to the instant exchange of specie for goods. The progress of wealth and industry is, however, necessarily accompanied by the growth of confidence and credit. Upon this new principle, commercial dealing is gradually extended; and in these circumstances, without the intervention of the money-dealer, there must be a continual and useless transportation of specie between all commercial towns. No debt can be discharged without a remittance in cash, and each separate transaction will require a separate remittance. To obviate these useless payments in detail, the business is naturally transferred to a separate class of dealers, by whom the whole debts and credits of the community, in place of being settled individually, are brought to a general balance, and it is only for the discharge of this balance, that it is necessary to remit specie. The arrangements by which this result is produced are exceedingly simple and obvious, and are now become so familiar, that they hardly require to be explained in detail.

Utility of Banks.

When, in the progress of wealth and improvement, certain individuals begin to acquire, from their increased wealth and their extended trade, the general confidence of the community, it will naturally occur to inferior traders, who have remittances to make to other places, that the great merchant, by means of his credit and connections, may assist him in his transactions with those distant parts. If the one has money to remit, the other may have money to receive, and in this manner, by means of credit and confidence, the engagements of the different parties may be duly discharged by a mere transfer of debt from one person to another. Thus, we may suppose A, the great merchant, has money to receive from the same place to which B, the inferior merchant, has money to remit. He receives the money from B, giving him, of course, an order on the debtor which he has in the same place in which B's creditor resides. To this place the order being sent, the debt belonging to A is transferred to the creditor of B. And thus, by the mutual transfer of claims, without the intervention of specie, this account of debt and credit is finally settled. The credit and connections of the wealthy merchant, inducing others to deposit money with him for the purpose of being remitted to their respective creditors, the cash transactions of the town and neighbourhood gradually centre in his hands. All those who have money to remit, or money to receive, entrust the transaction to his management; he receives their money, for which he gives them his drafts, or their bills, for which he either gives them money, or undertakes to procure payment, and, in this manner, the debts and credits of the different commercial towns, in place of being settled as formerly in detail, are, by the agency of the money-dealers, brought into one general account, and reduced at once to a common balance. The establishment of such public banks as those of Venice, Genoa, Amsterdam, Hamburgh, &c., on the solid security of large deposits of treasure, by inspiring general confidence, would tend to give life and activity to this improved system of money-dealing. The credit of an individual, however respectable for wealth, integrity, and prudence, could hardly be supposed in any case to be equal to that of those public establishments which were the general depositaries of all the floating capital of the community, of which the management was committed to directors publicly chosen, and bound down in their

conduct to certain general rules, from which they have no discretionary power to depart. In the two great sources of mercantile confidence, therefore, namely, the reputation of wealth and prudent management, those institutions could not be exceeded. They were evidently beyond the reach of all the ordinary casualties of commerce, and it could only be by foreign invasion, or by some great internal convulsion, which would tend to the dissolution of all civil order, that their ruin could be accomplished. Their bills and drafts possessing a proportionably extensive circulation, formed a species of currency in universal credit, throughout the great mercantile community of Europe, and furnished a most convenient instrument for settling, in the most easy and expeditious manner, the cash transactions between distant parts.

It has been suggested, that those bills of exchange and drafts were the invention of the Jews, and such may very possibly have been the case. But the just and philosophical remark of Mr Dugald Stewart, in regard to the invention of printing, may be generally applied to the progress of mankind in all other arts and sciences. On this subject, he observes, that to whomsoever the credit of this important discovery may be due, it is evident, from the state of society at that time in Europe, and from the rapid progress of all moral improvement, that some such process, for the speedy dissemination of knowledge, must have been discovered about this period. The general condition of the world, created, if we may so express ourselves, an effectual demand for the discovery; and the ingenuity of mankind being turned to this object, the necessary means for gratifying the love of knowledge and inquiry, now fairly awakened, were speedily devised. In like manner, it may be remarked of bills of exchange, that the gradual progress of mankind in wealth and improvement, favoured the growth of mercantile confidence, which was still farther strengthened by the establishment of public banks of undoubted credit; and that, by whomsoever bills of exchange were first used, some such invention was the necessary result of that increased confidence and credit, which the progress of wealth and industry was rapidly diffusing over all Europe.

In general, the public banks established throughout Europe were found to answer all the purposes of their institution. As their credit was beyond all question, they afforded a solid foundation for commercial confidence, and their affairs being managed with prudence, they increased in respectability and credit, supplying the home merchant with a safe and convenient instrument of exchange, and enabling the foreign merchant to receive remittances from abroad, or to make his payments more cheaply, safely, and expeditiously than before. In addition to those already mentioned, other banks were established in different parts of Europe, and upon the same model. But, in some cases, owing to a deviation from their original rules, and to an imprudent extension of their concerns, from a desire of inordinate gains, they were occasionally in want of specie, and being unable to pay on demand, they fell from that high degree of credit, which is essential to the usefulness and prosperity of such institutions.

By the general circulation of the bills of those public banks, the use of specie was in a great measure superseded as a medium of exchange between distant parts; and it was obvious, that, by following out the same principle in the domestic circulation of a country, paper might, in like manner, be substituted for specie in its internal commerce. When a debt against persons of undoubted ability to pay is once constituted by a written document, the debt may, by means of this document, be made over to liquidate the claims of a third party, and in this way, a cumbersome species of paper currency may be employed in the great transactions of trade. By improving the form of this instrument, however, by circulating bills for small sums, and by making them payable on demand, a public bank, in good credit, will supply the community with a paper currency so convenient as to answer all the purposes of specie.

Establishment of the Bank of England.

In the course of the last century, public banks for the circulation of paper in lieu of specie have been established in most of the great cities of Europe. Of these, the most important, whether we consider its great wealth, or the vast extent of its transactions, is the Bank of England. Of the nature and origin of this establishment, an account will be found in the *Encyclopædia;* and, in this supplementary work, we shall proceed, briefly, to notice some of its more recent transactions, and also to describe generally the effects produced by so powerful an engine on the circulation and commerce of the country.

Transactions with the Government.

The Bank of England, when it was first incorporated, assisted Government with a loan of L. 1,200,000, and it has subsequently been in the practice of accommodating the public, from time to time, with loans to a considerable amount. In 1746, those advances, which form its undivided capital, amounted to L. 11,686,800, for which interest is paid by Government at the rate of 3 *per cent.*; and its divided capital had been, at the same time, raised, by different calls and subscriptions, to L. 10,780,000. The state of these two sums continued nearly the same till the year 1800, when the Bank, in consideration of the renewal for twenty-one years of its charter, which expired in 1812, advanced to Government a farther sum of L. 3,000,000, without interest, for six years. This sum became payable in the year 1806, at which period, it was agreed, after some discussion, that the loan should be continued to Government during the war at an interest of 3 *per cent.* In the following year, in consequence of the great profits arising from the vast and increasing amount of the public money deposited in the Bank, the Chancellor of the Exchequer claimed for the public some compensation, either by an annual payment of money, or by a loan without interest. In the year 1797, the deposits of cash in the Bank, whether belonging to the public or to individuals, amounted altogether to L. 5,130,140. The Government balances alone had increased, in the year 1807, to the enormous amount of between L. 11,000,000 and L. 12,000,000; and, in consideration of the profit accruing to the Bank from the use of this money, its directors agreed to lend L. 3,000,000 to Government without interest, until six months after the conclusion of a definitive treaty of peace. This loan, together with the former loan of

L. 3,000,000 granted in 1806, became due in the year 1814. The loan of 1806 was discharged, but the loan with which Government was accommodated in 1808 was continued to the public till 5th April 1816. According to an arrangement made at this time, the Bank was allowed to add to its capital L. 2,910,600; and in return the loan of L. 3,000,000 was continued at an interest of *3 per cent.* An additional advance was also made to Government of L. 6,000,000, at an interest of 4 *per cent.* The debt of the Government to the Bank has been in this manner increased from L. 11,686,800 to L. 20,686,800.

Circulation of the Bank of England.

The following view of the state of its circulation at different periods, from 1718 to the present year (1816), is extracted from accounts laid before Parliament.

Amount of Bank of England Notes in Circulation at the following Periods.

In the Year	Notes of L. 5 and upwards.	Notes under L. 5.	Bank Post Bills.	Total.
1718.	L. 1,829,930			L. 1,829,930
1721.	2,054,780			2,054,780
1730.	4,224,990			4,224,990
1754.	3,836,870		L. 186,920	3,975,870
1761.	5,863,290		138,520	6,001,810
1762.	6,012,150		119,620	6,131,770
1763.	6,716,660		173,020	6,889,680
1772.	5,881,960		319,070	6,201,030
1778.	7,030,680		509,390	7,540,070
1783.	6,354,070		353,470	6,707,540
1784.	6,074,930		317,800	6,392,730
1791.	10,027,600		661,910	10,689,510
1792. Average of Jan. and July	10,277,990		724,865	11,102,855
1793. Average of Jan. and July	11,193,105		735,005	11,928,110
1794. Average of Jan. and July	9,670,450		576,130	10,246,586
1795. Average of Jan. and July	9,580,300		559,605	10,139,905
1796. Average of Jan. and July	9,516,000		590,165	10,106,165
1797. January	8,742,530		461,970	9,204,500
July	9,331,920	L. 921,780	524,400	10,778,120
1798.	9,571,945	1,483,740	506,045	11,561,730
1799.	10,135,265	1,526,890	561,385	12,223,540
1800.	11,385,380	1,704,880	723,525	13,813,785
1801.	12,913,460	2,439,650	816,760	16,169,870
1802.	12,541,675	2,939,730	762,710	16,244,115
1803.	10,978,655	3,243,595	748,920	14,971,170
1804.	11,763,035	4,564,415	739,225	17,066,675
1805.	11,319,370	4,509,034	933,970	16,762,374
1806.	11,491,765	4,255,130	685,495	16,432,380
1807.	11,295,215	4,062,770	677,965	16,035,950
1808.	12,264,170	3,987,720	667,385	16,919,275
1809.	12,881,095	4,442,500	782,260	18,105,855
1810.	14,627,680	5,990,695	834,555	19,452,930
1811.	13,522,210	7,209,700	1,049,470	21,781,380
1812.	15,238,425	7,594,605	1,048,680	23,881,710
1813.	14,996,635	7,712,135	977,335	23,686,105
1814.	16,214,830	8,313,380	1,089,340	25,517,550
1815.	16,522,530	9,065,890	1,215,100	26,803,526
1816. April	16,096,950	9,135,000	1,362,410	26,594,360

Flourishing State of its Affairs.

Notwithstanding the embarrassments to which the Bank of England has been occasionally exposed from the fluctuations of commerce, and from the effects of political alarms, the amount of its capital, and the extent of its transactions, have been gradually increasing, and the wealth which it has now accumulated is greater, perhaps, than was ever before engrossed by any other trading corporation. Previous to the year 1797, the state of its affairs was not generally known to the public. But at that period its affairs having been submitted, in consequence of the suspension of its cash payments, to the investigation of

a Parliamentary Committee, it appeared that, besides paying a dividend generally of from 5½ to 7 *per cent.*, it had accumulated a fund of undivided profits amounting to L. 3,800,000. Since the year 1797, its affairs have been even in a more flourishing condition than at any former period. Its circulation has been increased from L. 11,000,000 to L. 27,000,000; its transactions have been extended, and its profits have been augmented in proportion; while the law releasing it from the obligation of paying in specie, by rendering it unnecessary to keep in reserve so large a stock of cash, has tended greatly to increase its command of active and productive capital. It has been already stated that the Bank, besides transacting the ordinary business of discounting mercantile bills, is also employed as a great engine of State,—receiving and paying the interest due to the public creditors,—circulating exchequer bills,—accommodating Government with immediate advances on the credit of distant funds, and assisting generally in all the great operations of finance. In its capacity of public banker to the State, the Bank has an allowance for the management of the national debt; it has an allowance of L. 800 *per* million on the whole amount of every loan of which it receives the payment; upon every lottery contract, it is allowed L. 1000; and, lastly, it has the use of all the public money committed to its charge, besides several other allowances of less importance. The sum paid for the management of the public debt has varied according to circumstances. In the year 1726, under the economical administration of Sir Robert Walpole, L. 360 *per* million was paid to the Bank on this account; the allowance was afterwards increased to L. 562, 10s. *per* million. But, in the year 1786, when the public debt amounted to L. 224,000,000, it was reduced to L. 450 *per* million, at which rate it continued till the year 1807, when, in consequence of the vast increase of the public debts, it was still farther reduced to L. 340 *per* million, on the first L. 600,000,000 of debt, and to L. 300 *per* million on the excess beyond L. 600,000,000; at which rate it still continues.

Business transacted by the Bank for Government.

In the course of the two last wars, the business transacted by the Government at the Bank has increased far beyond its former extent. The debts of the country, on the management of which the Bank receives a commission, have risen from L. 224,000,000 to about L. 830,000,000. In the year 1792, the sum paid to the Bank for the management of the public debt, and for receiving the contributions on loans and lotteries, amounted to L. 99,803; while, for the year ending 5th April 1815, the sum paid for the same service amounted to L. 281,568, being an increase of L. 181,765. During the same period, the public deposits of cash at the Bank, in consequence of the increased pecuniary transactions of Government, have been accumulating in a similar proportion. In the year 1792, these deposits could not have amounted to L. 4,000,000. Since that time they have been rapidly increasing; and from the year 1806, the average amount may be stated at between L. 11,000,000 and L. 12,000,000, on which the Bank have been receiving interest at the rate of 5 *per cent.* As a compensation for the use of this money, the Bank, as has been already stated, lent to Government L. 3,000,000, at an interest of 3 *per cent.*, and afterwards an additional L. 3,000,000 without interest. The gain of the public on these transactions being deducted from the annual interest on L. 11,000,000 of the public money, the profit of the Bank on this branch of its business will be found to have amounted, since the year 1806, to nearly L. 382,000 *per annum.*

Wealth accumulated by the Bank.

From all these different causes, therefore, from the increased circulation of its notes, and from the vast accumulation of public business, the profits of the Bank appear to have been prodigiously augmented in the course of the late war, so that its average dividend, including the *bonus* from time to time added to it, will be found to amount, from the year 1797, to nearly 10 *per cent.*; and it is calculated besides, on data which admit of no considerable error, that the sum of undivided profit must, in the meantime, have increased to the enormous amount of L. 13,000,000. * Out of this fund the Bank has advanced to Government, for the year 1816, a loan of L. 6,000,000; and at a court of proprietors, held in May 1816, it was resolved to make an addition to the capital of the Bank of L. 2,910,600, the effect of which is to raise the capital of each proprietor of L. 100 of stock, producing at present L. 10 *per annum*, to L. 125, and to increase his income proportionally, *i. e.* to L. 12, 10s. *per annum.*

Advantages resulting from the use of Paper in place of Specie.

The great profit realized by the Bank since the suspension of its cash payments, has produced a corresponding rise in the value of its stock. Throughout the year 1797, the average price of Bank stock was about L. 125 *per cent.* Since this period it has been gradually improving in value, and its market price now amounts to about L. 262 *per cent.* The original capital of the Bank has thus acquired, since the year 1797, when the act passed releasing it from its obligation of paying in specie, an additional value equal to nearly L. 16,000,000; which, added to the estimated increase in the sum of its undivided profit, amounting, according to Mr Ricardo's calculation, to L. 9,599,359, makes a sum of L. 25,599,359, the actual improved value of the Bank capital during the last nineteen years.

One great inducement to establish a bank for the circulation of paper in place of specie is, that it provides a cheap instrument of exchange in place of a more expensive one, and from the obvious advantage of such an operation, both to the individual and to

* This view of the affairs of the Bank, since the year 1797, is founded on the statements contained in the work of Mr Ricardo. He seems to have made his calculations on grounds sufficiently certain, and his capacity for diligent research leaves little room to question his accuracy. The amount of the surplus capital accumulated by the Bank in 1797, which is the foundation of all the subsequent conclusions, is ascertained from the account of its affairs laid before Parliament, at the time of the suspension of cash payments in 1797. See Ricardo's *Proposals for a Secure and Economical Currency, Appendix*, No. V. p. 103.

the community, paper, after it is once introduced, is gradually found to limit, and at last entirely to supersede, the use of specie in the circulation of a country. Such has been the progress of paper in the currency of Britain. Specie is now entirely excluded from circulation; all that portion of our currency which formerly consisted of the precious metals has either been exported, or is stored up by the bankers, by whom it is kept in reserve, to answer occasional demands. The establishment of one great bank in the capital of the country would facilitate the introduction into other parts of similar establishments, on a smaller scale. Such a bank is naturally a general reservoir of specie for the whole kingdom. Its transactions are of so much greater an extent than those of any other establishment of the same kind, that all the specie which it could collect at home would be insufficient to supply its wants. When its coffers are exhausted, therefore, they must be replenished from abroad. Bullion must be purchased in the great market of the civilized world, and the supply thus imported is gradually distributed, in the general course of circulation and commerce, among the lesser banks. The wants of those smaller establishments can always be supplied, to any extent, from the store of specie collected in the great bank; for they have only to convert a certain portion of their property into its promissory-notes, in order to procure the supply necessary to replenish their exhausted coffers.

Country Banks in Britain.

Since the establishment of the Bank of England, banks on a smaller scale have accordingly been begun in almost all the provincial towns of Great Britain. They seem to have increased with great rapidity in the course of that short interval of prosperity and peace which followed the American war. During this period, all the great branches of national industry were extremely flourishing—the capital of the country was daily augmenting—the principle of mercantile confidence, the natural effect of such a state of things, was in full vigour,—and spirited individuals, in every quarter, taking advantage of these favourable circumstances, proceeded to establish banks; and having thus created a currency on the foundation of credit, the precious metals were no longer required to carry on the circulation of the country. According to an estimate made by Mr Thornton,* which is rather moderate than otherwise, the number of country banks in Great Britain amounted, in the year 1797, to 353. In 1799, they had increased to 366, and, in 1800, to 386. About this period, they appear to have increased rapidly, for we find the number of licences granted in 1809, for the issue of promissory-notes in Great Britain, to have amounted to 785. In 1812, they amounted to 878; and, in 1814 and 1815, to about 1000. Of these, there are in London, besides the Bank of England, about 70 private banking-houses, and the remaining 930 are dispersed throughout the kingdom. To the management of these various money-dealers, the whole circulation of the country is committed. Their business consists in settling the cash transactions of distant places, and in issuing their notes, for the accommodation of trade, by discounting mercantile bills; and the arrangements which they adopt for this purpose are eminently calculated to promote the dispatch of business, and the economy of cash.

System of Banking in Britain.

We have already, in part, explained in what manner the establishment of accredited banks tends to simplify the cash transactions of distant parts, and it is obvious that a community abounding in bankers of established character and credit, whose promissory-notes and bills of exchange circulate, to the exclusion of specie, must possess ample means for carrying into effect all the refinements of money-dealing. In Great Britain, accordingly, the general progress of trade and manufactures—the known wealth of banking establishments—the security derived from the long continuance of domestic peace—the high state of commercial confidence—the facilities of communication, joined to other advantages peculiar to such an advanced state of society, have brought the system to perfection. By means of bills of exchange, circulated among the different bankers, remittances are made to the most distant parts with the most perfect security, and at an inconsiderable expence. The respective debts and credits of the great commercial towns, in place of being settled in detail, or by remittances in specie, are, by the agency of the money-dealers, collected into one general account, which is brought to a common balance, and in this way the most extensive transactions may be settled with a comparatively small quantity of specie. If we suppose, for example, one of the two trading towns of Glasgow and Manchester to export, to the other, goods to the amount of L.2,000,000 annually, and to receive a return to the value of L.1,900,000, those transactions being, through the medium of the bankers, brought into one general account, there remains only an undischarged balance of L.100,000. But the tendency of the system being to make the whole complicated transactions of an extensive country centre in one common account, it may not be necessary, even for this balance of L.100,000, to send a remittance of specie, seeing that it may be transferred, by a draft on some third place, to a more general fund of debt and credit, where it may be finally met and liquidated by opposite balances to the same amount. Thus, we may suppose the balance of L.100,000, due from Manchester to Glasgow, to be discharged by a draft on London. In this case, London comes in the place of Glasgow, as the creditor of Manchester, the transaction being substantially to transfer the debt to the general cash account of those two places. But Manchester, in consequence of a favourable balance of trade, may be the creditor of other towns, as well as the debtor; and London being credited with the money to be received, as it was formerly charged with the money to be paid, all these insulated transactions are brought into one general account, on which the balance is struck, and it is only for this last and final balance that cash must be provided. In this highly artificial and curious system, the wealthy and populous towns natu-

* See *Inquiry into the Nature and Effects of the Paper Credit of Great Britain*, p. 154.

Banking.

fally draw, as to a common centre, all the cash transactions of the neighbourhood; the insulated balances, arising on the commerce of the surrounding country, are formed into new accounts by the money-dealers of these towns, who, by a simple transfer of debt and credit in their books, bring them to a general balance. This balance they afterwards carry to a still more general account; and thus, at length, all the scattered debts of the country are collected into one common account by the bankers of the metropolis, which is then brought to a final balance. The metropolis, the centre of intercourse and trade, is the centre, also, of this vast system of money-dealing. Here, as to a point, all the cash transactions of the country naturally converge, and here the account is finally closed by payments in cash.

In this manner, all the money-dealing of this country, which cannot be transacted without remitting specie, is transferred to London. The payments of London, originating in its own extended commerce, and in its great wealth and population, are of themselves immense. These are still further increased by the payment of the interest on the national debt, which is issued every quarter from the Bank of England; and London having also, in the course of the late wars, grown up to be in some degree the commercial metropolis, both of America and of Europe, it has been found convenient to transfer the payment of foreign bills to it from all parts. In consequence of these extended transactions, London has its debtors and creditors in every quarter of the kingdom. It is the general centre of all money-dealing, and there being, on this account, a greater demand in the country for money in London, than there is in London for money in the country, bills on London are invariably sold in the money market of the country for a premium. The currency of every other bank is limited in its circulation within particular districts, and cannot, therefore, be employed in transacting the payments of distant places. But money in London is a commodity in universal request, and bills for its payment constitute a medium of exchange common to the whole country.

All the various money-dealers who are dispersed throughout the kingdom, require to be provided with a stock of this common currency in order to carry on their business, and, for this purpose, they find it necessary to establish a credit on the metropolis, on which, for a suitable premium, drafts may be obtained from them at all times. By thus transferring the payments of the country, to be settled in one general account in the metropolis, both the expence and trouble of making remittances between distant places has been greatly diminished. It would be interesting if we could collect any exact account of the progressive diminution which took place, in consequence of this improved system of banking, in the expence of managing the cash transactions of the country. But unfortunately those instructive facts which illustrate the progress and internal structure of society, though of far more real importance than the accounts of wars and battles, seldom attract the same attention. On this account, all traces of them are frequently lost before their importance is discovered, and the future inquirer finds himself reduced either to glean from oral tradition, or from the passing and imperfect records of the day, the scanty materials of domestic history. From some inquiries on this subject, made by a Committee of the House of Commons in 1780, we find, according to the evidence of several of the collectors, that, before this period, the mode of remitting the public revenue to the treasury was both irregular, cumbersome, and expensive. In Scotland there was no certain or regular channel of remitting to the metropolis, and the remittances were not only very uncertain as to the time, but the collectors, not being always able to procure bills, were frequently under the necessity of remitting to the Receiver-General the actual money which they had collected. In different parts of England the same difficulties had, at a former period, been experienced in the remitting of the public revenue. From about the year 1740, it appears, that a premium had been paid to those who undertook the charge of remitting the money, of from 20s. to 2s. 6d. *per cent.* This premium, as the country advanced in wealth and industry, was gradually diminished, and about the year 1778, it was entirely done away, the dates of the bills drawn on London being also at the same time shortened. In 1764, the collector of the Wales district paid 7s. *per cent.* for bills on London, and in 1774, a premium of 2s. 6d. *per cent.* was paid by the collector of Dorsetshire, for bills payable on London at 40 days date. Even so late as the year 1780, though the collectors found no difficulty in the remitting of the public revenue, it was chiefly from merchants and manufacturers that they procured bills on the metropolis. Only a small part of their remittances were made through the medium of the country banks, and in all cases security was required for the whole sum remitted. Since the general establishment of banks, and the consequent increase of commercial confidence, the largest sums are now remitted from the remotest parts with the most perfect regularity, and without either premium or security; the only advantage derived by the banker from the transaction, being the use of the money for a certain number of days, varying in proportion to the distance from London.

Mode of settling the daily Transactions of the Banks in London.

All those complicated payments of the country, which are transferred to London, are finally settled by the London bankers, with specie or with notes of the Bank of England, it being the practice to use no other currency in the payments of the metropolis; and in managing those extensive money-dealings, they still act upon the principle of collecting the insulated transactions of individuals into one common account, and this account is brought to a general balance. For this purpose a clerk, it appears, is dispatched from each banker, at an appointed hour in the afternoon, and a meeting of the whole having taken place in a room provided for the purpose, each clerk exchanges the drafts on other bankers, received at his own house, for the drafts on his own house, received at the houses of other bankers. The balances of the several bankers being then transferred from one to another, in a manner which it is unnecessary to explain in detail, the several accounts are finally wound up by each clerk into one balance, and it is only for this single balance that each banker has to provide specie

Banking.

or notes. By this contrivance, so great a saving of cash is effected, that though the daily transactions of those bankers are calculated to amount to nearly L. 5,000,000, about L. 220,000 of bank-notes is generally found sufficient for the discharge of the several balances due at the settlement of the account. Other devices are also put in practice by these active and ingenious money-dealers, for economising the use of cash. Many bankers are allowed to have a general cash-account with the Bank of England, in which, if they are careful to keep a supply of good bills, they may always procure whatever cash they require on a day's notice. For the same purpose also of preventing any waste of the circulating medium, accredited brokers are in the habit of hourly walking Lombard Street, and of borrowing the superfluous cash of one broker and lending it to another, for a day, a week, or any longer period, to be repaid when called for; and so nicely is the scale adjusted by those various devices, that the most opulent houses are frequently accommodated with a supply of cash before three o'clock, to be repaid by a draft at the general balance of accounts, which takes place in the afternoon.*

The recent policy of the Bank of England has also tended greatly to favour those economical contrivances of the inferior bankers. The daily demand made upon them by the Bank for the amount of bills accepted and payable at their several houses, is of course considerable, and was formerly made at an early hour, before the notes were issued for bills discounted on the same day, and without any previous notice to the bankers of the demands for which they might be liable, and of which they had no means of judging. For some time past the Bank has adopted a different practice, having notified the amount of the demand at an earlier hour, and taken payment at four in the afternoon, receiving for part of the sum such drafts or bills as the bankers may happen to hold in place of bank-notes.

In consequence of all those contrivances, the circulation of London is carried on with the smallest possible quantity of currency which is consistent with the regularity of its payments; and any sudden reduction, therefore, in the amount of its circulating cash, would ultimately lead to a state of general insolvency and suspension of confidence. Bills and drafts from all quarters of the country being also made payable in London, and accepted by the different bankers, and a failure in any one of those payments being deemed an act of insolvency, it is evident that any general derangement of credit in London must spread far and wide throughout the kingdom. The punctuality of the London payments is necessary to sustain and regulate the whole paper credit of the country; and these payments being made exclusively in Bank of England notes, the circulation of those notes cannot, in any case, be materially reduced with safety to the community. Prior to the restriction act, there was no risk of any undue increase in the circulation of bank-notes, as the excess would have been immediately returned in exchange for specie. But the Bank, being now released from its obligation to pay in specie, and being thus closed against any return of its superfluous notes, its circulation may be increased at the discretion of its directors; and, in these very peculiar circumstances, it is the opinion of Mr Thornton,† that the true policy of the Bank is generally to allow its circulation to vibrate within certain limits; to resort, when the temptation to borrow in the way of discounts is too strong, to some effectual principle of restriction, but in no case materially to reduce the sum in circulation; to afford a slow and cautious extension of it, as the general trade of the kingdom is enlarged; and to allow of a temporary increase, even beyond its usual limits, in a season of extraordinary difficulty or alarm.

Disadvantages incident to a Currency of Paper.

It is justly observed by Dr Smith, after he has explained all the advantages of banking, that the commerce and industry of a country cannot be so secure when managed with paper money, as when managed with a currency of gold and silver. "The gold and silver money which circulates in any country," he observes, "may very properly be compared to a highway, which, while it circulates and carries to market all the grass and corn of the country, produces itself not a single pile of either. The judicious operations of banking, by providing, if I may be allowed so violent a metaphor, a sort of waggon-way through the air, enable the country to convert, as it were, a great part of its highways into good pastures and corn-fields, and thereby to increase very considerably the annual produce of its land and labour. The commerce and industry of the country, however, it must be acknowledged, though they may be somewhat augmented, cannot be altogether so secure, when they are thus, as it were, suspended on the Dædalian wings of paper money, as when they travel about upon the solid ground of gold and silver. Over and above the accidents to which they are exposed from the unskilfulness of the conductors of this paper money, they are liable to several others, from which no prudence or skill of these conductors can guard them." (*Wealth of Nations.* Buchanan's edit. Vol. I. p. 508.)

The necessary effect of every system of paper currency is, to encourage the principle of commercial credit. This is, indeed, the foundation on which it is raised, and the more widely the circulation of paper is extended, the more closely will the mercantile community be knit together by the artificial ties of confidence and credit. Wherever there is trade, there must no doubt be credit. But where banks are generally established for the purpose of circulating paper money, credit must be augmented tenfold, seeing that, in such circumstances, no one can receive a payment without becoming a creditor. It is an evil, therefore, inseparable from any system under which a currency of the precious metals is supersed-

* Bonsanquet's *Observations on the Report of the Bullion Committee.*

† *Inquiry into the Nature and Effects of the Paper Credit of Great Britain*, p. 295.

ed by one purely conventional, that while a useless expence is thereby saved to the community, and while its capital also acquires an increased degree of activity, the trading part of society are brought into such a state of general dependence, that every man may be said, in some degree, to rest upon his neighbour, and the whole to rest upon the principle of confidence in each other. The banker's notes obtain a general circulation; no demand is made upon him for their payment in cash, because the public believe that he has property to pay them. The banker, in like manner, discounts the merchant's bills, from an opinion of his solvency, and the merchant, in giving credit, is guided by the same rule. Confidence, in short, is the charm which holds the whole together, and while this principle prevails, no evil will result from this complicated system of credit. Bank-notes will circulate freely—there will be no great demand for specie—and the merchant will always be enabled to convert his bills into cash. In these circumstances, every expedient will be adopted to spare the use both of notes and of specie. The merchant will naturally be anxious to reduce as low as possible the stock of cash which he reserves for occasional demands; in many cases he will trust to accident for providing funds, such as to the sale of his goods, or to his credit with his banker; while the banker, who provides a cheap instrument of exchange in place of a more expensive one, and whose profit consists in lending it on the same terms, has, in like manner, a strong inducement to increase the circulation of his paper, and, trusting to his credit, to diminish the specie reserved for its payment. While the system is in this manner strained to its utmost pitch, the merchants managing the commerce of the country with the smallest possible quantity of paper, and the bankers circulating the paper with the smallest possible quantity of specie, let us suppose, that from whatever cause, either from the alarms of war, or from a succession of bankruptcies, the principle of mercantile confidence begins to fail. In this case, the former ties by which merchants were connected with each other are now broken; the usual channels of circulation, by which a small quantity of cash rapidly passing from one hand to another, served for transacting the payments of the community, are interrupted, and the money in circulation is, in consequence, found insufficient for the punctuality of mercantile payments. The supply of currency, however, in place of being increased, is still further diminished; the bankers, from the fears natural to their situation, limiting the circulation of their notes, and refusing to accommodate the merchant, as before, by discounting his bills; and the public, in their turn, discrediting the paper of the banks. This general failure of confidence immediately produces alarming bankruptcies, many merchants stopping payments, not from a want of property, but from a want of cash; a run commences on the banks for specie, many of whom are, in consequence, obliged to suspend their cash payments. The Bank of England being the great repository of gold in this country, the demands of the country banks for specie gradually centre in the metropolis, the bankers generally disposing of the property which they hold in the public funds and other Government securities, and demanding from the Bank of England specie for whatever quantity of its notes they can collect. The Directors of the Bank, astonished by this alarming drain of their cash, naturally contract the circulation of their paper. But the transactions of the metropolis having been hitherto managed with the most exact frugality, both of notes and specie, this sudden diminution of its circulating cash must leave the money-dealers unprovided with funds necessary for their immense payments, and must thus derange the whole economy of that complicated system which has been raised upon the frail foundations of confidence and credit. The disorder arising in the metropolis, from a want of cash, will soon extend itself to the remotest extremities of the kingdom. In the mutual dependence created by credit and confidence, the failure of one merchant involves others in the same fate, bankruptcies multiply in every quarter, and the alarm increases with such rapidity, as to threaten a general subversion of credit and confidence throughout the country.*

Policy to be adopted by the Bank of England in a disordered state of the Circulation.

In such a disordered state of the circulation, all the inferior banks are naturally induced, from a prudent regard to their own safety, to limit the issue of their notes, by which means the scarcity of cash is increased, and the evil greatly aggravated. But the Bank of England cannot safely act on such a contracted policy; for it is evident, that the general discredit of bank-notes is occasioned by the alarm prevailing in the country, and that, while this alarm continues, the Bank may be drained of its specie by the most limited circulation of its notes, which will be returned upon it as fast as they are issued. In all such cases, therefore, the only safe course for the Bank to pursue, is rather to enlarge the circulation of its notes, that the alarm may be quieted, and that the supply of currency may be perfectly adequate to effect the daily payments of London, of which the punctual discharge is necessary to the solvency of the country at large. It is not to be wondered at, however, if the Bank, while the nature of paper circulation, and of the evils to which it is exposed, were but imperfectly known, should not always have understood its true interest, and should therefore have hesitated to embrace a policy so unusual, and apparently so hazardous. In the course of the year 1793, the country was agitated by a sudden and general alarm. The scarcity of money was extreme, and paper was discredited. Numerous bankruptcies took place, and there was a great demand among the country banks for specie, which the Bank of England was as usual ultimately called upon to supply. Embarrassed by the drain of its specie, the Directors of the Bank refused to accommodate several great and opulent country banks who applied for assistance, and they were also unwilling to augment the issue of their paper. Immediate and important failures ensued, and the increasing alarm and distress for money in London, plainly showed that the relief of the

Interruption of Credit in 1793.

* Buchanan's edition of Smith's *Wealth of Nations*, additional volume, p. 99.

country was necessary to the solvency of the metropolis. It did not appear, that, at this period, the notes issued by the Bank of England were fewer than usual, but, owing to the failure of confidence among mercantile men, they circulated more slowly, and they became in this manner inadequate to transact the immense payments of London, with the same regularity as before.

The Bank of England, not deeming it expedient to enlarge the issue of its paper, a remedy of exactly the same nature was administered by Parliament. A loan of Exchequer bills, to the amount, if required, of L. 5,000,000, was directed to be made to as many merchants, giving proper security, as should apply. Such were the salutary effects of this measure, that the very expectation of a seasonable supply of what could be immediately converted into cash, diffused a general feeling of confidence; the punctuality of the London payments was restored, and the credit of the country began to recover. Of the sum proposed to be granted by Parliament, applications were made for L. 3,855,624, some of which being either rejected or withdrawn, the actual sum issued from the Exchequer amounted to L. 2,202,000, which was punctually repaid without either apparent difficulty or distress. The effect of this measure was to supply the community with a temporary currency, in place of that which had fallen into discredit, or which had been withdrawn from circulation by the caution of the banks; and its advantages were evinced by the speedy restoration of mercantile confidence, and by the increased facility of raising money, which was previously felt both in the metropolis and in the country at large. *

Interruption of Credit in 1797, and Suspension of Cash Payments by the Bank of England.

This state of confidence continued, with little interruption, until the year 1795. At this period, the Bank, in consequence of the large advances which it had made to Government, was under the necessity of retrenching the sum usually allotted for the discount of mercantile bills. A scarcity of cash was soon felt among the merchants and money-dealers of the metropolis, and the threatened invasion of the country, during the year 1796, concurred to spread a general alarm, which naturally gave rise to the discredit of bank-notes, and to a demand for specie. About this period, several banks in the north of England were under the necessity of suspending their cash payments, and the alarm of these failures soon reaching the metropolis, the Bank of England was subjected, about the beginning of the year 1797, to an alarming drain of specie, partly to supply the demand of the country banks, and partly from the return of its own discredited notes. In order to check this increasing pressure, the Bank diminished the circulation of its notes, which having, for several years before, amounted to nearly L. 11,000,000, and having been reduced, for some time, to between L. 9,000,000 and L. 10,000,000, were, at this particular period, brought down to between L. 8,000,000 and L. 9,000,000. From a combination of all these circumstances, therefore, namely, the alarm in the country—the discredit of country bank-notes—the pressing demands of those banks for specie, all centering in the metropolis,—and, lastly, the undue restriction of its issues by the Bank, such a scarcity of cash was produced in London, and such an alarm followed, that the run upon the Bank of England for specie, so far from abating, continued to increase with an alarming rapidity. In these circumstances, the Directors communicated to the Chancellor of the Exchequer an account of the precise reduction which had taken place in the amount of their cash, the consequence of which was, that an Order in Council was at length issued, on Sunday the 26th February, restraining the Bank from all further payments in specie. An act of Parliament was soon after passed, confirming the restriction on the cash payments of the Bank; and this principle has been since continued, by successive acts of Parliament. By the last act, passed in April 1816, it is continued for two years from that date.

An event so unlooked-for and unprecedented as a stoppage of payments by the Bank of England, produced, at first, a general feeling of astonishment and alarm; and as the executive government had interfered, on its own discretion, to suspend the obligations of the Bank to its creditors, it was necessary that the sanction of the Legislature should be obtained for this extraordinary exercise of power. The whole matter being therefore referred to the consideration of Parliament, long and anxious discussions took place, on the causes which had given rise to this great convulsion in the mercantile world, and on the policy to be pursued, in a state of things so wholly unexpected. Parliamentary committees were appointed, with power to examine the officers of the Bank, both as to the general state of its affairs, and as to the circumstances which led to its present embarrassments; and by the labour of these committees, joined to the able publications of individuals on the subject, such a precise and accurate account has been collected respecting all the facts of this extraordinary case, that it has not only been made clear in itself, but a new and steady light has been thrown, by the information disclosed, on the general principles of paper currency. We shall briefly consider, on these general principles, to what causes this memorable suspension of cash payments by the Bank of England was chiefly owing.

Dangers to which Banks of Circulation are exposed.

It is obvious, from the very nature of banking, that the stock of specie reserved by a bank for the payment of such demands as may be made upon it, cannot bear any proportion to the amount of its notes in circulation; and that, if a certain proportion of these notes should at any time be suddenly returned for payment, a suspension of its cash payments must be the inevitable consequence. This is an evil inherent in the very nature of paper currency, against which no caution can duly provide, since the profit of the banker is exactly in proportion to the

* *Report of the Commissioners to the House of Commons.* Thornton *On Paper Credit*, p. 51. Buchanan's edition of Smith's *Wealth of Nations*, additional volume, p. 102. *Edinburgh Review*, Vol. IX. p. 193.

excess of his circulating paper over the specie reserved for its payment.

A bank, and more especially a national bank, may be subjected to demands for specie from either of the two following causes: 1st, From an unfavourable balance of trade; or, 2dly, From domestic alarm.

1. When the imports of a nation exceed its exports, a balance of debt will remain due to foreign countries; and in the country which owes the balance there will be a greater demand for money abroad than for money at home. If the unfavourable balance of trade continues, the demand for money abroad, with which the balance may be discharged, will increase, and foreign money, or bills on foreign bankers, will be sold for a premium. In this case, there arises a temptation to export the coin of the country, which, from the state of trade, has become more valuable abroad than at home; and where a national bank is established, whose notes are convertible into cash at the will of the holder, it may undoubtedly be exposed, by an unfavourable balance of trade, to demands for specie to a considerable amount. But, in the nature of things, the drain of specie from this cause must be slow and gradual, and where a bank has ample funds wherewith to purchase specie, it can hardly ever, in this case, be driven to the exceptionable measure of suspending its cash payments. The Bank of England has frequently been exposed, from this or from similar causes, to a regular drain of its specie; but its credit was in no danger from those demands, because its coffers could always be replenished as fast as they were exhausted. Prior to the great recoinage, in 1774, the gold currency of this country was in a very debased state; the market price of gold rose, in consequence, above its mint price; and the value of bank-notes was lowered to the standard of the debased coin, for which they were currently interchanged. In these circumstances, it was a profitable transaction to procure bank-notes for their nominal price in light and worn guineas, and to return them upon the Bank for the same nominal price in guineas of their standard weight, which last were melted down and sold for bank-notes at the market price of bullion; and these notes were immediately returned upon the Bank in exchange for a new supply of standard guineas, to be again melted and sold. In consequence of this state of the currency, the Bank of England was subjected to a constant and regular drain of its specie, and to a very great annual expence in replacing the guineas of which it was drained. But there was no risk that this drain, however expensive and troublesome, would ever lead to a suspension of its cash payments, because it was regular and gradual, and subject to calculation; so that, as long as the Bank had wherewithal to purchase guineas, they could always be provided in sufficient quantity to answer the demand.

In like manner, though a public bank, from an unfavourable balance of trade, or from a great expenditure abroad, may undoubtedly be exposed to an inconvenient drain of its specie, it seems scarcely possible that this drain can be so rapid as to endanger its credit. It is not in the nature of trade to produce any such sudden and unexpected crisis. The operations of trade always leave time for some previous arrangement, and they have generally some respect also to the convenience of all the parties concerned. It is well known, for example, that in the case of a heavy accumulation of foreign debt, from whatever cause, the balance is more frequently discharged by an exportation of goods than of specie. The effect of foreign debt is to depress the exchange; an unfavourable exchange, or, in other words, the high price of money abroad, operates as an inducement to export goods; the exporter, besides his usual profit, gaining an additional profit equal to the difference of the exchange. It will always be observed, therefore, that a great foreign expenditure is very soon followed by a large exportation of goods, and though specie may be partly remitted for its discharge, the produce of the country is found to answer the purpose equally well. From the year 1793 to 1797, the foreign exportation of this country on the Continent of Europe and to the West Indies, amounted to L. 33,510,779;* and in consequence of these heavy expences abroad, the Bank was subjected to demands for specie to a considerable amount. But though the Directors of the Bank, in their correspondence with the Government, complain heavily of the loss of specie which the Bank had experienced, and though, in February 1796, they even go the length of formally recording it as their opinion, that any farther advance to the Emperor of Germany, or any foreign state, would be fatal to the Bank, † this opinion seems evidently to have been the result of undue apprehension, and to have been expressed strongly for the purpose of deterring the Chancellor of the Exchequer from persevering in his system of lavish advances to foreign powers, the effect of which, they justly conceived, would be injurious to the Bank, by subjecting it to a farther and very inconvenient drain of its specie. But since, in the course of the three several years of 1794, 1795, and 1796, the foreign expenditure of the country amounted to something more than L.8,000,000, L.11,000,000, and L.10,000,000, without injuring the credit of the Bank, it can hardly be believed that an additional expenditure of L.3,000,000, or even L. 4,000,000, could have given such a sudden shock to its credit, as to have occasioned the suspension of its cash payments. Nor do the Directors, although they express generally their uneasiness at the drain of their specie, ev[illegible] to have contemplated such a catastrophe. O[illegible]ry, the Governor and Deputy-governor, when exam[illegible]d before the Secret Committee of the House of [illegible]ds, state that they did not apprehend imminent da[illegible] previous to the 21st February 1797.‡ From these circumstances, therefore, it appears that the

* *Report of the Lords' Committee of Secrecy, Appendix*, p. 107.

† Copy of a *Resolution* of the Court of Directors of the Bank of England, 11th February 1796. See *Report of the Lords' Committee of Secrecy*, p. 80.

drain of specie to which the Bank was subjected in consequence of the great foreign expenditure of the country previous to the year 1797, or in consequence of any unfavourable balance of trade, though constant, was confined within certain limits; that provision could have been made for it; and that, though it imposed on the Bank a certain annual expence, yet, with due exertion to procure the necessary supplies of specie, it could never have been fatal to the credit of so great an establishment.

2. The drain of specie to which a great national bank may be subjected from the prevalence of a general alarm, is in all respects different from that which may be produced by a great foreign expenditure, or by the fluctuations of trade. The impulse given by panic is, in its very nature, sudden and instantaneous. It generally terminates also, and that speedily, in some violent crisis. If we suppose, therefore, that a bank, which circulates its notes extensively, suddenly falls into discredit, that from some unknown cause, a sudden suspicion of its solvency seizes all the holders of its notes, it is obvious that all these persons, under the violent impulse of their fears, will rush at once to the bank with notes in exchange for specie; and it is equally certain, that whatever funds a bank may ultimately possess, its stock of specie must be speedily exhausted by such a sudden inundation of its discredited notes. In this case its cash payments must be suspended for a time, until the alarm of its creditors be dissipated by a full disclosure of its affairs. Such being the fatal operation of domestic alarm on the credit of a bank, it can scarcely be doubted that this was the immediate cause of the catastrophe which befel the Bank of England in 1797; more especially, as we find that it was exposed for more than two years to the drain of specie occasioned by foreign expenditure, without any injury to its credit, while one single week or little more of domestic alarm, terminated in a suspension of its cash payments. On Tuesday the 21st February, the Directors of the Bank were so alarmed by the increasing demand for specie, that they communicated to the Chancellor of the Exchequer the precise reduction which had taken place in the amount of their cash. In the course of the preceding week, the drain of guineas had been considerable; but after Tuesday the 21st, it continued increasing with the most alarming rapidity, insomuch that, according to the evidence of the Directors, the demand for specie, on the two last days of the week, exceeded that of the four preceding days. This is the great and conclusive fact, which points at once to the cause of the ruin which was impending over the Bank. It was not so much the actual loss of specie which excited apprehension, its cash having been lower both during the American war and in the year 1782; but the unparalleled rapidity with which the drain increased, was the alarming circumstance which defied all precautions, and which finally rendered the suspension of cash payments by the Bank an act of overruling necessity. Its stock of specie had no doubt been previously reduced by the demand arising from an unfavourable balance of trade, and this would naturally tend to bring matters more speedily to a crisis. But however well replenished the Bank might have been with specie, the demand was increasing at such an accelerated rate, that, in the course of a few days more, it would have been quite sufficient, without the help of any other cause, to have drained it of its last guinea. *

---

* That the embarrassments of the Bank were occasioned by the demand at home is plain, from the following evidence of Mr Giles and Mr Raikes, before the Lords' Committee of Secrecy:—

Mr Giles was examined as follows:—

" Has the Bank of England lately experienced an unusual drain of cash?—Most certainly.

" Are you able to ascertain how far this drain was wholly, or in part, occasioned by demands for cash from different parts of the country?—It was owing, in great part, to demands from the country: indirectly from the country, but directly from the bankers in London (who are to supply the country) upon us.

" Whether, by the effects of this drain, the balance of cash remaining in your hands has been reduced considerably below the amount at which it has usually been maintained?—The cash of the Bank has, of late, been considerably reduced. I have known it a great deal lower; but, on this occasion, the demands have been unparalleledly rapid; they have, of late, been progressively increasing, but, in the last week, particularly so; and we had every reason to apprehend that these demands would continue, and even increase.

" Whether such reduction had been continuing in an increased proportion to the balance remaining in your hands up to the date of the minute of Council transmitted to you?—We have generally answered this question in our preceding answer; but, we beg leave to add, that the demands have been progressively increasing in the course of the last week, and in the last two days exceeded the demands of the four preceding days."

Mr Giles and Mr Raikes were examined as follows:—

" Do you think the restriction made by the order of Council of the 26th of February was necessary?—Certainly.

" Do you consider it as necessary to the interest of the Bank?—The rapid drains we had upon the Bank, and the continuance of them, made us think it advisable to communicate to his Majesty's Ministers the situation of the Bank, that they might, in their wisdom, use such means as they might think expedient.

" When was that communication made to the Chancellor of the Exchequer?—We think the first was on Tuesday the 21st of February; the drains not only continued but increased, and so rapidly the last day or two, that we communicated it to the Chancellor of the Exchequer on Saturday, and had the honour to meet his Majesty's Ministers on the Sunday.

Banking.

Reasons for continuing the Suspension of Cash Payments by the Bank of England considered.

The act restricting the Bank of England from paying its notes in specie, or rather the act by which it obtained this privilege, was, when it was first passed, justified by the necessity of the case. The alarm was so general, that no other expedient remained to save the credit of the Bank. But all sudden and violent alarms are in their own nature of short duration; and when the Parliamentary inquiry, which was commenced into the affairs of the Bank, disclosed in its favour a large balance of accumulated profits, all suspicion of its solvency, and all farther alarm, was immediately done away. In these circumstances, the privilege of refusing specie for its notes being still continued to the Bank, it was necessary to justify this proceeding on different grounds from those urged in favour of the original measure; and with this view, Mr Thornton, the great advocate of the Bank, insists, that, to have enforced the resumption of cash payments, after they were once suspended, at any subsequent period of the last war, would have endangered the credit of the Bank as much as when the first restriction act was passed;—that, after the conclusion of peace, the country was embarrassed by an unfavourable balance of trade, proceeding chiefly from the necessity of making large importations of corn, in order to supply the deficiencies of two successively bad crops,—that the Bank must, in consequence, have been exposed to a continual drain of its specie,—and that the restriction on its cash payments was, therefore, still necessary, as a security against this danger.

We have already endeavoured to show, that the drain of specie to which an unfavourable balance of trade may subject the Bank, can never be such as to endanger its credit, because, in such cases, the demand is neither so rapid nor so considerable as to preclude the Bank from providing the necessary supply of gold. Where trade is in such a state, indeed, the Bank will be exposed to a considerable annual expence in procuring specie. The punctual and honourable discharge of its obligations to the public will frequently be found to be both inconvenient and expensive, and its Directors will naturally be desirous to be free from that which increases responsibility, and diminishes profit. But, unless in the case of a general alarm, and discredit of bank-notes, it does not seem that a suspension of cash payments can ever be necessary to the safety of a bank. It deserves to be considered also, that an unfavourable balance of trade, accompanied by an unfavourable exchange, is in its own nature of short duration. It is an evil which tends to redress itself; a large importation of goods, necessarily leading to an exportation in the same proportion. But, although it is not consistent with the plan of the present article to enter fully into the subject for the consideration of which at greater length other opportunities will occur, we may observe, that the foreign exchanges of a country may be influenced by the state of its currency at home, as well as by an unfavourable balance on its foreign trade; and as it is of the first importance to mark the distinction between an unfavourable exchange proceeding from the state of trade, and an unfavourable exchange proceeding from the state of the currency, since the least want of accuracy in this essential point must throw the whole subject into confusion, it is material to remark, that the unfavourable state of the exchange, and the demands for specie to which the Bank was in consequence exposed, which are urged by Mr Thornton as reasons for continuing the restriction on cash payments, have always been ascribed by those who deny the necessity of that restriction, not to the state of trade, but to the depreciation of the paper, in consequence of that over-issue which they maintain to have taken place very soon after the Bank was released from its obligation of paying in specie. Mr Thornton insists, * that if the Bank had been opened to demands for specie, it might, in consequence of the unfavourable state of the exchange, have been exhausted of its cash; and that, to guard against this, it was still necessary to continue the suspension of its cash payments. According to the opposite hypothesis, it is maintained, that the state of the exchange, to which Mr Thornton refers, was connected not with the state of the trade, but with the state of the currency,—that the Bank being now closed against any return of its notes, had issued them in excess,—that having, in consequence, fallen in value, it became profitable to return them upon the Bank for specie,—that the demand for specie, of which the advocates of the Bank complain, was in reality produced by the depreciation of its own notes,—and that the reasons, therefore, assigned by Mr Thornton for the continuance of the restriction, rather prove the necessity of reinforcing on the Bank the obligation of paying in cash, by which means its currency being restored to the value from which it had fallen, the demand for specie would have ceased; and Bank-notes and specie would have been demanded indiscriminately. The one would have answered all the purposes of the other, and the business of the country would have been transacted, as before, with a mixed currency of paper and of gold. It is not to be supposed, indeed, that there were no such occurrences in the history of the country, previous to the year 1797, as unfavourable balances of trade, large importations of corn, in consequence of scarcity, and heavy foreign expenditure, in consequence of war. The Bank, from the time of its first establishment, has had to encounter all the fluctuations incident to peace or war. It has also been exposed to drains of specie from unfavourable balances of trade, as well as from the debased state of the

---

"Were not the drains from Tuesday the 21st of February to the Saturday inclusive, much greater and more rapid than they had been in the whole of the preceding week?—Certainly; they were unexampled.

"Did you apprehend imminent danger previous to Tuesday the 21st?—We cannot say we did.

"When did you first apprehend imminent danger?—We cannot say we apprehended any imminent danger, but from the fears of the drains continuing. Not wishing to risk the drains continuing, we submitted it to the Chancellor of the Exchequer."—*Report of the Lords' Committee of Secrecy.* Minutes, March 1797.

* *Inquiry into the Nature and Effects of the Paper Credit of Britain*, p. 115.

Banking.

currency; but it was not until the year 1797, that its Directors, as a security against those inconveniences, bethought themselves of the singular expedient of dishonouring their own notes. In former periods too, the credit of the Bank was nearly subverted by domestic alarm. A case of this nature occurred in the reign of Queen Anne, when, from the apprehension of a French invasion, the Bank was assailed by an alarming demand for specie. The alarm, however, as is usual in all such cases, soon passing away, the credit of the Bank was entirely re-established, and payments in specie were of course continued during the remainder of the war. The Directors did not venture upon the bold step of making a temporary alarm a pretext for the permanent suspension of their cash payments. They reserved this extreme remedy for extreme cases, not thinking it applicable to those ordinary casualties to which all banks are necessarily exposed.

Bank of England Notes made legal tender.

At the time when the Bank of England suspended its cash payments, a law was passed, protecting a debtor who offered its notes in payment against arrest, though his creditor, by a common action of debt, might still recover payment in guineas, the legal currency of the country. In 1810, when guineas began to be currently sold for 25s. and 26s. in paper, a law was passed prohibiting this traffic, and imposing severe penalties on those who should exchange bank-notes for less than their nominal value in gold. Tenants, who offered payment of their rents in bank-notes, were at the same time protected against distress, though they were still liable to a common action of debt or of ejectment. In 1811, in consequence of a great landed proprietor announcing that he would exact payment of his rents in guineas, an act was passed, protecting a debtor who offered Bank of England notes in payment of his debt against all farther proceedings. The paper of the Bank of England became, in this manner, legal tender for all existing debts, however depreciated it might be in its value, and the law conferring upon it this important privilege still continues in force.

Chartered Banks of Scotland.

In Scotland, banking has been generally carried on with great prudence and success. There are at present, in the metropolis of Scotland, three banks incorporated by charter, namely, the Bank of Scotland, established by act of Parliament in 1695; the Royal Bank, established by royal charter in 1727; and the British Linen Company, originally incorporated in 1746, with a capital of L.100,000, for the encouragement of the linen manufacture, but afterwards converted into a bank, for the issue of promissory-notes, and the discounting of bills. Those different banks, besides their annual dividends, have been accumulating a fund of undivided profit, which they have, from time to time, been adding to their original capital. The Bank of Scotland and the Royal Bank, have each a capital of L.1,000,000, with an additional L.500,000 subscribed for, but which has never been called up. The capital of the British Linen Company was lately increased from L.200,000 to L.500,000.

Of the country banks in Scotland, it may be remarked, that in most cases they have been established on the security of ample funds; and having conducted their affairs with prudence, they have generally increased their original capital, and on this account have acquired a great degree of respectability and credit. It is a well known fact, that among the Scotch banks failures have been much less frequent than among the country banks in England.

Bank of Ireland.

In no country, perhaps, has banking been carried to such an injurious excess as of late years it has been in Ireland. The national Bank of Ireland was established in 1783, with an original capital of L.600,000, raised by subscription, which was lent to government at an interest of 4 *per cent.* It was placed under the management of a governor, deputy-governor, and fifteen directors; eight of whom, including the governor and deputy-governor, were to form a court of directors, for managing the concerns of the Bank. They were eligible every year, and it was provided that one third, at least, of the directors should be annually changed.

In 1809, the Bank of Ireland obtained a renewal of its charter for twenty-one years, on condition that its capital should be increased by L. 1,000,000 of stock, to be raised from the proprietary at the rate of L. 125 *per cent.*, and to be lent to government at 5 *per cent. per annum.* The Bank also agreed to continue the management of the public debt and loans, free of expence to government, during the continuance of its charter.

In 1797, when the Bank of England suspended its cash payments, the same privilege was extended to the Bank of Ireland, and after this period its circulation was rapidly increased. The following is an account of the amount of its notes in circulation at different periods:

1797	L. 621,917
1801	2,266,471
1802	2,678,980
1803	2,633,864
1804	2,986,999
1805	2,902,438
1806	2,465,710
1807	2,818,140
1808	2,732,483
1809	3,141,410
1810	3,192,186

This increased circulation of paper appears to have exceeded the wants of the community, since it was followed by rise in the price of bullion, and by the depression of the exchange. About the year 1804, this evil had proceeded to such an extent, that guineas were openly advertised and sold for a premium of 10 *per cent.*, and the exchange with London was about 17 *per cent.* against Dublin. From this depreciation of the notes of the national Bank many serious evils arose. The silver currency, which circulated in Ireland, was generally in a debased state, and the intrinsic value of the different coins was not equal to the value for which they were current. But by the fall which had taken place in the notes of the Bank of Ireland, those debased silver coins became more valuable in the form of bullion than in the form of currency. They

3

Banking.

were, accordingly, all melted down, and the community being in consequence exposed to the greatest inconvenience, their place was supplied in Dublin and other parts by counterfeits, and in several districts by a paper currency, issued for sums gradually decreasing from 6s. to 6d., and even to 3d. It is calculated by several persons, who gave evidence before a committee of the House of Commons in 1804, that, about this time, there were dispersed throughout Ireland 295 issuers of this paper money, chiefly consisting of a motley body of shopkeepers, merchants, and petty-dealers of all descriptions. The country was inundated with this exceptionable currency, and it was the occasion of such general inconvenience, as well as of such numerous forgeries and frauds, that the circulation of notes for such small sums was at length prohibited by law. Notwithstanding the prohibition, those notes still continued to circulate, the law was evaded by various contrivances, and the want of a better currency secured their circulation. The Bank of Ireland has since made an issue of stamped dollars, which, by supplying the wants of trade, has, in a great measure, remedied the evil complained of.

The premium on guineas, which, in 1804, was 10 *per cent.*, has since greatly declined, and the foreign exchanges of Ireland have also become more favourable. In 1808, guineas were exchanged for paper at a premium of 8d., and paper has since risen nearly to par. As the Bank of Ireland has increased, in place of diminishing, its circulation, since 1804, the cause of this rise in the value of paper must be sought for in the retrenchment of the notes of other banks. It appears, accordingly, that the number of provincial banks has, of late years, been very considerably diminished in Ireland, and that of fifty banks which issued notes in the year 1804, not more than nineteen remained in 1812, the others having either failed or withdrawn from business. * The extinction of so large a portion of the currency would necessarily increase the value of what remained in circulation.

The price of Irish bank-stock has been greatly improved in value within the last twenty years. The following is an account of its price at different periods:

1798	January	90 *per cent.*
1799	January	115
1802	January	179
1804	January	140
1810		189
1816	September	214

Dividend on Irish bank-stock at different periods.

1798	$6\frac{1}{2}$ *per cent.*
1801	$6\frac{3}{4}$
1803	$7\frac{1}{2}$
Bonus in 1803	5
1816	10

Bank of France.

In France the progress of banking, as of every other domestic improvement, was retarded by the convulsions of the revolution. But in the year 1803, when the peace of the continent appeared to be secured, and tranquillity prevailed at home, the different banks in Paris were consolidated into one great national bank, called the Bank of France, by an act of the imperial government. The act establishing this bank fixed its capital at 45,000,000 francs, equal to L. 1,875,000 Sterling, to be divided into 45,000 shares of 1000 francs each. It was vested with the exclusive privilege of issuing promissory-notes, payable on demand, in consideration of which, it made large advances to government. Its business was to discount bills of exchange, notes, or bonds; but it was prohibited from carrying on any commerce, except in cash or bullion. The administration of the Bank of France was committed to fifteen directors and three censors, and to these was added a council of discount, consisting of twelve of the principal merchants in Paris, who were to have the privilege of a vote in all matters relative to the discounting of bills. The great body of the proprietors were represented by 200 delegates, chosen from among those possessed of the greatest number of shares, who were to meet annually, or oftener if they were required. To this assembly the affairs of the Bank were to be annually submitted, and the members of the council of discount were to state, whether, in granting discounts, the directors had conformed to the general rules established to regulate their proceedings. These 200 representatives were also to elect the directors, of whom three, and the censors, of whom one, were to be annually changed. It was provided that the dividend for the year (1804) should not exceed eight *per cent.*, to be paid half-yearly, and that whatever profit remained should be invested in the public funds, and allowed to accumulate as a fund of reserve against contingencies. The exclusive privileges of the Bank were granted for fifteen years, commencing from the year 1804.

Under these regulations, the Bank of France commenced its operations; and during the first year of its establishment, its profits amounted to 4,185,937 francs (L. 174,414), being rather more than 12 *per cent.* upon its original capital. Of this sum, 8 *per cent.* was divided among the proprietors; the remainder was invested in 5 *per cent.* stock, as a fund of reserve; and in the following year, the net profit amounted to 4,652,398 francs (L. 193,850). In the latter part of the year 1805, the Bank of France was considerably embarrassed by the drain of its specie, which, in 1806, continued to increase with such rapidity, that the Bank was obliged to suspend its cash payments. Various causes are assigned for this catastrophe, which seems to have chiefly originated in the necessity of making large remittances of specie to the armies then engaged in the Austrian war—in the great advances of the Bank to the Government—in the over issue of its notes—and finally, in vague and unfounded alarms which generally prevailed respecting its solvency. Its notes fell from their standard value, and were exchanged at a discount for specie. The exchange with the country of France became at the same time unfavourable to Paris, to the amount of 12 *per cent.*; and the Bank having restricted its discounts, several important bankruptcies took place, which

* Wakefield's *Statistical and Political Account of Ireland*, Vol. II. p. 171.

tended greatly to increase the general alarm.* After the peace of the Continent was re-established by the treaty of Presburg, the advances made by the Bank to the government were punctually repaid, and payments in cash were resumed about the commencement of the year 1806. In the course of this year also, in consequence of a decree of the imperial government, a change took place in the administration of the Bank. In place of fifteen directors, its affairs were committed to a governor and two deputy-governors, who were to be appointed by the Emperor. At the same time, its capital, consisting of 45,000 shares of 1000 francs each, was increased to 90,000 shares, or to 90,000,000 of francs.

The new shares were disposed of by the Bank to great advantage, and in consequence of this accession to its capital, it was enabled considerably to extend its operations. By an imperial decree issued at Bayonne, in the year 1808, it was authorized to establish branches in some of the chief provincial towns; and establishments of this nature were begun at Lyons and Rouen, for the purpose of circulating bank-notes, and of discounting bills of exchange. But the merchants of these towns, though they willingly received accommodation from the banks, showed no disposition to circulate their notes. Almost all the notes issued were immediately returned on the Bank for payment; and it is worthy of remark, that neither the notes of the ancient *Caisse d'Escompte*, nor those of the present Paris Bank, have ever obtained any general circulation in the country of France.

In 1814, when France was invaded by the combined armies of Europe, the Bank of Paris was called upon to make large advances to government, and, at this period, its notes in circulation, joined to its other engagements, exceeded by about 20 millions of francs the value of the specie, and other effects of which it was possessed. A general alarm began to prevail; the Bank was exposed to a ruinous drain of its specie; and on the 18th January a resolution was adopted, not entirely to suspend its cash payments, but to limit the sum to be paid in cash to 500,000 francs *per* day, and not to pay more to each individual than 1000 francs. In February the Bank, having made the necessary arrangements, resumed its payments in cash for all sums, and during the siege and capture of Paris, it continued to pay in cash, even while the cannon thundered at the gates of the city. In like manner, during the subsequent invasion of the country in 1815, payments in cash were not, nor have they ever been since suspended even for a day.

In all the trying situations in which they have been placed, the Directors of the Bank of France appear to have displayed a laudable zeal to fulfil their engagements to the public. This bank, like the Bank of England, has frequently been employed as a great engine of state; its funds have been diverted from their proper purposes to assist in the great emergencies of the public service; and its directors, yielding to the pressure of temporary demands, have been forced, for a time, to suspend their payments in cash. But the Bank of France has always resumed the ordinary course of its payments as soon as the alarm and the demand for specie began to abate; while the Bank of England, having once obtained a dispensation from its obligations to the public, seems ever since to have been intent on securing the continuance of this privilege. The example of the Bank of France, which, though it suspended its cash payments, in consequence of the pressure arising from domestic alarm, resumed those payments as soon as the alarm began to subside, may serve to expose the insufficiency of the arguments urged in this country in favour of the continued suspension of cash payments by the Bank of England. The circumstances of the two banks appear to have been precisely similar, and no reason can be imagined to justify the one more than the other in continuing to refuse payment of its notes.

The following is a statement of the affairs of the Bank of France on the 12th August 1816: †

	Francs.	*L.*
90,000 shares of 1000 francs (L. 45 each), -	90,000,000	4,125,000
Fund of undivided profit,	21,600,000	990,000
	111,600,000	5,115,000

Investment of this Capital.

	Francs.	*L.*
In the 5 *per cent.* Consol. (from which a revenue is derived of 2 millions),	33,500,000	1,395,834
In shares of its own, which it has repurchased (which has the same effect as if, by the rules of its institution, the number of shares had been more limited),	25,500,000	1,062,500
Advances made to government on treasury-bonds, or other securities bearing interest, -	26,000,000	1,083,333
Property, - -	4,000,000	166,666
Specie and bills, - -	22,600,000	941,667
	111,600,000	4,650,000

* *Considérations sur L'Institution des principales Banques de L'Europe, particulièrement sur celle de France.* Par M. Monbrion. 1805. *Rapport fait à la Chambre de Commerce par une commission speciale sur la Banque de France, et les causes de la crise qu'elle a eprouvée.* 1806.

† The Editor was enabled to furnish the Writer of this article with some of these particulars in regard to the Bank of France, and with this statement of its affairs, by means of a communication kindly made to him by M. Jean-Batiste Say, dated at Paris, on the 14th August last (1816). M. Say is well known as the Author of *Traité d'Economie Politique*, in 2 vols. 8vo, a work, perhaps the most generally sound, instructive, and comprehensive, that has been published on that important science since the appearance of the *Wealth of Nations.*

Debts owing by the Bank of France on the 12th August 1816:

	Francs.	L.
The amount of its notes in circulation, - -	70,000,000	2,916,667
Amount of deposits, - -	20,000,000	833,334
	90,000,000	3,750,000

For this sum the Bank has either specie in its coffers, or good bills, generally at the short date of 45 days. If we add to this the sum of 22,600 francs in bills and specie, already stated as part of its capital, it follows that the Bank of France, on the 12th August 1816, was possessed of effects to the amount of 112,600,000 francs (L. 4,691,667). Of this sum it had 41,000,000 francs in hard cash.

The following is an account of the dividends from 1806 inclusive:

	Profit Divided.	*Profit Undivided.*
	Francs.	Francs.
1805-6.	72 *per cent.*	·80
100 *Days of* 1806, *to December* 31.	20	2 ·40

1815.	64	2
1816. *half-yearly dividend.*	36	3

American Banks.

In the United States, banking has of late years kept pace with the general progress of wealth and improvement throughout the country, and banks have, in consequence, been established in all the most considerable towns. In 1804, they were calculated, according to the most accurate computation that could be made, to amount to eighty, including ten subordinate banks; and the capital invested in this business was estimated at 50,000,000 of dollars. †

The principal American bank is that of the United States, which was incorporated by an act of the Legislature in 1791. By this act, it is provided, that the capital stock shall consist of 10,000,000 dollars, in 25,000 shares of 400 dollars each, one-fourth to be paid in specie, and three-fourths in 6 *per cent.* stock. The bank is restricted from taking more than 6 *per cent.* on their discounts, or from advancing more to government than 100,000 dollars. It declares half-yearly dividends, which, from its establishment, have been 4 *per cent.*, with two surplus dividends, one of 1 *per cent.*, and the other of 2 *per cent.* The date at which it discounts bills is two months.

The late war in which America was involved with Great Britain, seems to have occasioned considerable disorder in the state of her circulation. From the speech of the President to the Congress, in December 1815, it would appear, that the public finances and trade of the United States had been exposed to great inconvenience from the want of some uniform national currency, and from the disappearance of the precious metals. To remedy these evils, it was purposed to establish a new bank at Philadelphia, on the security of such ample funds as should engage universal confidence, and should thus give its notes a free circulation through every part of the United States. A bill, for this purpose, was passed in the last Session of Congress, and it is understood, that the capital required has been since subscribed. (o.)

BANKS FOR SAVINGS. The institutions pointed out by this designation constitute a variety of money-banks, in general, and, to a certain extent, partake of the nature of the class.

Of money-banks, in general, the end is to afford to the owner of money two advantages; the first, safe custody for his money; the second, a profit by it, under the name of interest. Other advantages which banks afford, or are capable of being made to afford, it is not, for the present purpose, necessary to bring to view.

Objects of this class of Banks.

The circumstances of the poor man lay him under many disadvantages, as compared with the rich. In this case, we find a particular example. The money of the rich man, being in considerable quantity, easily finds individuals who will perform for it the functions of banking, because it yields an adequate profit.

The money of the poor man, being small in quantity, can find nobody to perform for it the functions of banking, because it is incapable of yielding an adequate profit.

Let us consider the natural tendency of this situation of the labouring man. He can make no profit by money retained. He also lies under many chances of being unable to preserve it. The coarse and imperfect means for shutting his house, or any receptacle which it may contain, exposes his little treasure to the hand even of a clumsy depredator. Accordingly, we find, that persons in the lower situation of life, who acquire a reputation for the possession of hoards, are almost always robbed. If they are disposed to lend the

* To make out this dividend, 194,238 francs were taken from the fund of undivided profit.
† See *Economica, or Statistical Manual for the United States of America*, p. 159, 160.

Banks for Savings.

fruit of their industry and frugality, their limited experience of mankind makes them yield to the man who takes most pains to persuade them; and that is often the man who never means to pay them again, and who has, therefore, the strongest motives to take the measures necessary for gaining their confidence.

Money is for two purposes. It is either for present use, or future use; and wisdom directs that it should be employed for the one or the other, according as, in either case, it is calculated to contribute most to happiness upon the whole. But the poor man is thus deprived, in whole, or in part, of the means of applying his money to *future* use. To this extent, therefore, even wisdom itself would direct him to employ it for *present* use, in whatever way it is capable of adding most to his enjoyments. Parsimony in such a case is hardly a virtue.

The rich are commonly, we cannot say always, very severe observers of the conduct of the poor, and nearly as often unjust. How nearly universal among them are the exclamations against the improvidence of the poor! by which is meant the practice of devoting to present use the whole of their earnings, without reserving as great a portion of them as possible to future use. Amid these exclamations, the degree is totally forgot, in which the poor are deprived of the means of reserving money for future use, and the consequent propriety and prudence of devoting it wholly to present use.

If human happiness is prodigiously improved by reserving for future use a proportion of the command which, over and above the necessaries of life, a man may possess over the means of enjoyment, it is surely desirable that this great instrument of happiness should, in the greatest degree possible, be provided for the most numerous, and in the same degree in which the most numerous, the most important portion of the race. To place it in the power of this portion of the race to secure a share of the good things of life for future use, a system of banking, adapted to their circumstances, is evidently, in the present state of society, in the highest degree desirable. It is one of the means, without which, or something equivalent, the end cannot be obtained.

The question, respecting the utility of banks, adapted to the circumstances of the labouring branch of the population, being thus decided, it only remains, as should seem, to inquire, what is the sort of institution by which the advantages of a bank,—safe custody, and profit for money, can be most completely secured to this great class of the population. When this second question is resolved, the subject, it may be supposed, would be exhausted. The supposition, however, would be erroneous, and the exposition would still remain very imperfect, and even superficial.

When it is ascertained, that banks for the cash of the poor would be useful to the poor, we should act very carelessly, if we remained contented with a mere vague conception of utility in general. To complete the inquiry, we should trace the subject in its ramifications, and pursue them to the very point of termination. We should not be satisfied with a belief that banks will, to some degree, and in some way, we know not what, be useful to the poor. We should ascertain, with accuracy, in what way or ways, and in what degree, they will tend to increase the happiness of this principal branch of the population.

Banks for Savings.

This is rendered more necessary, by the conduct of those who have chiefly undertaken the patronage of banks for this class of the population. They have been too lavish in their promise of beneficial effects from this desirable institution. They have stretched the vague idea of utility to any extent which suited their imaginations. There is nothing desirable for human beings which they have not described as the natural product of banks for the poor. Happiness and virtue are two things which they will be sure to produce in any quantity we please.

But when gentlemen treat us with these extraordinary promises of good from Savings Banks, they take not sufficient pains to show the connection. They neglect to inform us how the events are to come about. They do not show in what manner, if the one set of things precede, the other things which they so largely predict, must all of them follow. Now, this is not satisfactory. This is to assume and affirm, not to disclose. This is to beg the question, not to resolve it. This way of proceeding not only removes no uncertainty, it has a tendency to draw men upon false ground, and to recommend to them measures for practice founded upon mistaken notions of things, and therefore pregnant with the chances of evil.

Different Views of the Utility likely to result from Savings Banks.

The first part of a sound and rational inquiry into the subject of Savings Banks would thus undoubtedly be, to *define* the utility which the institution is calculated to produce; to ascertain exactly the ingredients of which the composition is formed, and the quantity in which it may be expected to exist.

For this purpose, it may be remarked, that the effects calculated to arise from the institution of Savings Banks are of two sorts; 1st, the immediate; 2dly, the derived. The first result at once from the operations of the Bank. The second arise only from the first, and are, in reality, the effects of the effects.

1. The effects of the first stage,—the effects which immediately result from the operations of the Bank, are two,—safe custody for the money deposited, and interest upon it.

Of these effects no general exposition is required. They are known and familiar to every body.

2. The effects of these effects come next under review. They are more complicated, and far less easy to understand.

It is expected that safe custody for money, and a profit by it, in the shape of interest, will produce a disposition to accumulate. This is the second stage. From this, other effects, which may be called effects of the third stage, are expected.

The disposition to accumulate will produce industry and frugality, which implies temperance. This is the third stage, and these are effects of the third derivation.

Industry and frugality will produce a reserve of wealth. This is the effect of the fourth stage, or fourth derivation.

This reserve of wealth will produce an effect of the fifth stage, namely, security against the miseries of want.

The utility consists in these latter effects, the industry and frugality, the provision against the miseries of want. These, then, are the ingredients of which the compound is formed. The question is, in what degree it may be expected to be produced: in other words, what power can the banks in question possess to produce among that class of the population industry, frugality, and a provision against the miseries of want? It is the resolution of this question which is required at the hands of every one by whom is undertaken an account of a system of banking adapted to the circumstances of the poor.

It is impossible to speak with any accuracy of the circumstances of the most numerous class of the people, without bearing in view the principle of population, or the law according to which the multiplication of the species takes place.

This law is by no means of recent discovery. It had long in political philosophy been regarded as an established fact, that a nation is always peopled up to its means of subsistence; that the only check to population is the want of food; that mankind, as Burke somewhat ingeniously expressed it, "propagate by the mouth;" and that the number of men, if food were not wanting, would double, as the example of America proved, every twenty or five and twenty years. But after establishing this doctrine, the world seemed a long time afraid to look it in the face, and glad to leave it in the situation into which it had been brought. At last, a period arose when men of a certain description began to talk intemperately about the opinion, that the human condition was progressive, and susceptible of indefinite improvement, and men of another description began to be alarmed at this doctrine.

In opposition to the persons who spoke with enthusiasm of this susceptibility of improvement, under the name of the perfectibility of the human mind, Mr Malthus brought forward the principle of population. It was not enough for his purpose to say, that population ascended to the level of food; because there was nothing in that relation inconsistent with improvement, or opposite to the principles of perfectibility. He went, therefore, a step farther, and said, that population rose beyond the level of food; a situation in which vice and misery must of necessity prevail, and unlimited progression was impossible.

Though no part of the doctrine of Mr Malthus has been left uncontested, it is now, among thinking men, pretty generally allowed, that, excepting certain favourable situations, as in new countries, where there is unoccupied land of sufficient productiveness, which may be placed under cultivation as fast as men are multiplied, a greater number of human beings is produced than there is food to support. This, it is understood, is the habitual condition of human nature. The disposition of mankind to marry, and the prolific power with which nature has endowed them, cause a greater number of human beings to be born than it is possible to feed; because the earth cannot be made to increase her produce so fast as the procreative power of the human constitution increases consumers.

This is the proposition which Mr Malthus added to the doctrine of population; and it is undoubtedly a proposition of extensive import, pregnant with consequences of the greatest moment, and materially changing our views of the measures necessary to be pursued for improving the condition of mankind.

It is perfectly evident, that, so long as men are produced in greater numbers than can be fed, there must be excessive misery. What is wanted then is, the means of preventing mankind from increasing so fast; from increasing faster than food can be increased to support them. To the discovery of these means, the resources of the human mind should be intensely applied. This is the foundation of all improvement. In the attainment of this important end, it is abundantly plain that there is nothing impracticable. There is nothing which offers any considerable difficulty, except the prejudices of mankind.

Of this doctrine, one of the facts which it is on the present occasion peculiarly necessary to carry in view, is the mode in which the misery in question, the misery arising from the existence of a greater number of human beings than there is food to maintain, diffuses itself.

For a share of the food which is brought into existence, the greater part of mankind have nothing to give but their labour. Of those who are endeavouring to purchase food by their labour, there is not enough for all; some must want. What is the consequence? Those who are in danger of being left out in the distribution, offer more labour for the same quantity of food; that is to say, they agree to work for less wages; by this competition, the wages of labour are reduced, and made so low that they are not sufficient to procure food for the families of all the labourers. The whole are placed in the lowest and most afflicting state of poverty; and of those whose wants are more than usually great, or supply more than usually small, a portion must die, from the want of a sufficiency of the necessaries of life. The state of wages is sufficient to afford the means of existence to as many as the food produced can barely preserve alive; the superabundance, who, by their competition, have rendered thus miserable the situation of the rest, must inevitably perish. Whatever the state of production in regard to food, the wages of the labourer are sufficient to enable the labourers, as a body, to raise a number of children sufficient to keep up the population to the level of the food. The labourer who has the number of children correspondent to that increase, has just enough to keep his family alive, and no more. Those who have a greater than this number, and not a greater than the usual means of procuring food, must partially starve.

This is the natural unavoidable condition of the greater part of mankind, so long as they continue to produce numbers greater than can be fed. The question then is, what are the effects which, in this situation of mankind, the institution of banks for the savings of the poor are calculated to produce?

Every thing, as we have already seen, is to be derived through the medium of the disposition to accumulate.

But the disposition to accumulate, as far as men are wholly deprived of the means of accumulation, is out of the question; for either it is wholly incapable of existing, or exists to no manner of purpose.

Of the labouring people, however, who have families, all but those of whom the families are uncommonly small, or who possess uncommon advantages, are, according to the principle of population, either in a state of starvation, or upon the very brink of it, and have nothing to accumulate.

The unmarried part of the population, therefore, those who have no families, or those who have very small ones, are those alone to whom the institution of savings banks can present any motives whatsoever. The question is, what are the effects which will be produced upon society by the motives which it presents to this reduced part of the population?

That it will increase to a certain extent the disposition to accumulate, may naturally be expected. To how great an extent, general principles afford us no means of very accurately foreseeing. We must wait for experience to determine. In the meantime, we know that single persons are for the most part young; and that youth is not the season when the pleasures of the present moment are most easily vanquished by those of the future. The training of the human mind must be more skilful, and more moral to a vast degree, before this salutary power will belong to any considerable portion of the youth in any class of the population, especially in the least instructed of all.

Let us next inquire the tendency which it will possess, whatever the degree in which it may be expected to exist.

In the first place, it will produce an abstinence from such hurtful pleasures as are attended with expence. Under this description is included the pleasure of intoxicating liquors, and no other possibly whatsoever. There is hardly any other indulgence on which any portion, worth regarding, of the earnings of the poor is bestowed, which can at all deserve the name of hurtful, or from which there would be any virtue in abstaining, if the means of obtaining it were enjoyed in sufficient abundance. To this, then, the moral effect of savings banks may be supposed to be very nearly confined. But assuredly this, if it can be produced in any considerable degree, must be regarded as an effect of no ordinary importance.

Passing from the moral effects, we come to the accumulation which it may be in the power of the unmarried part of the population to make. To this, and what may spring out of it, all the remaining effects of savings banks are evidently confined.

A part of the unmarried population will make accumulations, and undoubtedly they ought, if possible, to be provided with the means of doing so. Let us suppose that the greatest part of them profit by those means. What consequences are we able to foresee?

Of unmarried persons there are few who are not looking forward to the married state, and few by whom, sooner or later, it is not entered. As soon as persons of the lower class are married, or, at any rate, as soon as they have a certain number of children, their powers of accumulation cease. But there is a previous hoard: What becomes of it?

It is either wholly expended, at the time of marriage, upon the furnishing of a house; or it is not.

If it is wholly expended upon the furnishing of a house, it contributes to present enjoyment, like any other expence whatsoever; like that, for example, of a fine coat; and forms no longer a provision against a day of adversity and the evils of want.

Let us suppose that it is not wholly expended upon the furnishing of a house, but that a portion, at least, of it remains. This, it will be said, is reserved as a provision against want; and of this the beneficial effects may be reckoned sure. But abstracting from extraordinary cases of bad health, least common in the earliest stage of the married life, and other extraordinary accidents, the first pressure will arise from the increase of the family. After that number of children is born, which exhausts the earnings of the father, the birth of another child produces the miseries of want. If there is no fund remaining from former accumulations, hardship introduces death, and the amount of the population is thus, upon the whole, kept down to the level of the food. If there is a fund remaining from former accumulations, it will now of necessity be consumed; and by its consumption will enable the family to go on a little longer; to rear a child or two more. But the number of children reared was before as great as there was food to maintain. If a greater number is raised, there is an excess of population, who bid against one another for employment, and lower the wages of labour. Already, the great mass of the population were in a state of unavoidable misery from the lowness of wages. An increase of poverty is now brought upon them; and their situation is rendered more deplorable than it was before. It is impossible not to consider this as one of the effects, which a fund accumulated before marriage, by the laborious part of the community, has a tendency to produce. And this is a tendency altogether noxious.

The greater part of those who have talked and written about savings banks have left the principle of population altogether out of their view. They have, therefore, left out of their view that circumstance on which the condition of the most numerous class of mankind radically, and irremediably, and almost wholly depends. Of course, their observations and conclusions are of little importance.

Others, whose minds are philosophical enough to perceive the influence of the principle of population upon the condition of the great bulk of mankind, are of opinion, that savings banks will have a salutary effect upon the principle of population, and ameliorate the condition of mankind, by lessening the rapidity with which they multiply. This is a speculation of the deepest interest. If this be an effect of savings banks, they will, indeed, deserve the attention and patronage of the philanthropist and the sage.

The following is the mode in which the authors of this opinion believe that the happy effects which they anticipate will take place. The means of profiting by the reserve of a portion of their earnings,

Banks for Savings.

which savings banks will provide for the unmarried part of the labouring people, will give them, it is supposed, a taste for accumulation: Aware of the impossibility of accumulating after marriage, their desire of accumulation will make them defer the period of marriage: Of deferred marriages, the result will be a less numerous offspring: A smaller number of people in proportion to the food will be reared: The competition for food will be reduced; the competition for hands will be increased; wages will rise; and the cruel poverty of the mass of the population will be abated.

In this deduction, nothing is doubtful, unless the commencing step. If the desire created in young persons for accumulation is sufficiently strong to produce any considerable postponement of the period of marriage, all the other effects will necessarily follow; a reduced number of children; an increased reward of labour; and a correspondent amelioration in the condition of the greatest portion of the race. Savings banks will prove one of the most important inventions, to which the ingenuity of man has yet given existence.

It would be rash, however, to claim as an ascertained fact, that savings banks will have the effect of retarding the period of marriage. There are persons who hold the very opposite belief. They say, that what chiefly retards marriage at present among the better part of the labouring population, among those who have a regard to appearance, and a value for respectability, is the want of means to provide the furniture of a house; that savings banks will enable them to provide that furniture at an earlier period than at present; and that the institution will therefore accelerate the period of marriage, increase the number of those who cannot be fed, and thus add to the calamities of mankind. They ridicule the idea, that the love of saving will become, in the breast of young persons, a match for the passions which prompt them to marriage.

If we consider accurately what takes place among mankind, we shall probably conclude that both effects will be produced; that the love of saving will, no doubt, induce some persons to defer the period of marriage; but that the means of furnishing a house, placed at an earlier period within their reach, will produce the very opposite effect in regard to others.

The question is, which class is likely to be the most numerous? and this is plainly one of those questions to which no very certain answer can be given. But if we consider the strength of the passions which urge to marriage, we shall probably suspect that it will not be easy for the love of saving to acquire an equal force in the breast of any considerable portion of persons who are young, whose education has been very bad, and who hence have little power either of foresight or of self-command.

Such are the different views which may be taken of the effects which banks for the savings of the poor will produce. The exposition is useful to check the intemperate conclusions of enthusiastic patrons, and to show that much more than the mere institution of savings banks is necessary to produce any considerable amelioration, either in the physical or moral state of the poor. In conjunction with other causes, savings banks are not only desirable, but necessary. The noxious consequence will be, if those who have it in their power to do more, shall suppose that savings banks are sufficient to do all, and there should limit their exertions. Taken by themselves, it is at least a doubt whether savings banks may not produce as great a quantity of evil as good.

History of Savings Banks.

It now remains that we should give an account of the measures which have been taken for the establishment of savings banks, and endeavour, if we can, to ascertain the most useful form which they are capable of receiving.

We are not aware that the idea of an institution, answering in any degree the description of a savings bank, was in this country expressed in public before the year 1797, when a peculiar scheme for the management of paupers, or persons deprived of the means of maintaining themselves, was published by Mr Bentham in Young's *Annals of Agriculture*. It would require too long a digression to give an account of this plan of Mr Bentham, which embraces a great number of points, and would require an exposition of considerable complexity. Of that plan, one part consisted in the institution of what he distinguished by the name of a *frugality bank*.

The series of wants to which it was by him destined to operate as a remedy, were as follows:

1. Want of physical means of safe custody, such as *lock-up* places; thence, danger of depredation, and accidental loss.

2. Difficulty of opposing and never-yielding resistance to the temptations afforded by the instruments of sensual enjoyment, where the means of purchasing them are constantly at hand.

3. Want of the means of obtaining a profit by the savings of the poor, or the use of them in portions adapted to their peculiar exigencies.

4. Want of a set of instructions and mementos constantly at hand, presenting to view the several exigencies, or sources of demand for money in store, and the use of providing it.

He next proceeded to sketch the properties which appeared to him to be desirable in a system of frugality banks, commensurate to the whole population of the self-maintaining poor. These were,

1. Fund, solid and secure.

2. Plan of provision all-comprehensive.

3. Scale of dealing commensurate to the pecuniary faculties of each customer.

4. Terms of dealing sufficiently advantageous to the customer.

5. Places of transacting business suitable; viz. in point of vicinity, and other conveniences.

6. Mode of transacting business accommodating.

7. Mode of operation prompt.

8. Mode of book-keeping clear and satisfactory.

In the plan, however, of the bank which Mr Bentham contemplated for answering the purposes which he thus described, he did not direct his view to that simplest of all the forms of banking, the mere receipt of money, to be paid again with interest when demanded; the form to which the patrons of savings

Banks for Savings.

banks at present appear judiciously to confine their attention. Mr Bentham's proposal was to receive into the frugality banks the deposits of the poor, not for the mere purpose of yielding an interest, and being withdrawn when wanted, but to form or purchase an annuity for old age, when the power of earning would be either destroyed or impaired.

That the accumulation of the poor might not, however, be confined to one exigency, though that the greatest, he proposed that this superannuation annuity should be convertible, in the whole or in any part, into any other species of benefit, adapted to the exigencies of the owner. It might, for example, be converted into an annuity for an existing wife, in the event of widowhood. It might be converted into an annuity during the nonage of a certain number of children. It might serve as a pledge on which to borrow money. Part of it might be sold to raise a marriage fund, or it might be simply withdrawn.

Mr Bentham then proceeded to compare the effects of a system of frugality banks with those of friendly or benefit societies. To this comparison, however, we cannot with any advantage proceed, till that other species of institution is first described. We are, therefore, inclined to reserve it wholly to the article Benefit Societies, to which the reader is referred.

It is somewhat remarkable, that no allusion which we can perceive in any of the numerous pamphlets to which the subject of savings banks has lately given birth, is made to this early scheme of Mr Bentham; though the work in which it is contained not only appeared in a periodical and popular publication so long ago, but was laid upon the table of the committee of the House of Commons, appointed to inquire into the subject of Penitentiary Houses in 1811, and referred to in the appendix to their report; and was published separately in one 8vo volume, in 1812, under the title of *Pauper Management improved*.

As no attempt was made to carry Mr Bentham's plan of pauper management into practice, his scheme of a frugality bank, as a part of it, remained without effect.

The first attempt, as far as our researches have been able to discover, to give actual existence to the idea of a bank adapted to the exigencies of the poor, was owing wholly to a lady, to whom the public are indebted for several excellent productions of the pen, and who never took up her abode in any place, while health and strength remained, without endeavouring to perform something of importance for ameliorating the condition of those by whom she was surrounded. Mrs Priscilla Wakefield, the lady to whom we allude, residing, in the year 1803, at Tottenham, in Middlesex, a populous village, within a few miles of London, not only projected, but was the means of instituting, and the principal instrument in carrying on, a bank at that place for the savings of the poor. An account of this institution, drawn up by Mrs Wakefield, and dated the 24th of May 1804, was published in the fourth volume of the *Reports of the Society for Bettering the Condition of the Poor*. The account is so short, and so much to the purpose, that it may with advantage be inserted here.

Banks for Savings.

"Extract from an *Account of a Charitable Bank at Tottenham for the Savings of the Poor*, by Mrs Wakefield.

"For the purpose of providing a safe and convenient place of deposit for the savings of labourers, servants, and other poor persons, a charitable establishment has been lately formed at Tottenham, in the county of Middlesex. It is guaranteed by six trustees, who are gentlemen of fortune and responsibility, most of them possessing considerable landed property. This renders it as safe and certain as institutions of this kind can be, and insures it from that fluctuation of value to which the public funds are liable. The books are kept by a lady, and never opened but on the first Monday in every month, either for receipts or payments. Any sum is received above one shilling; and five *per cent.* is given for every 20s. that lies 12 kalendar months; every person so depositing money being at liberty to recal it, any day the books are opened; but no business is transacted at any other time.

"The money so collected is divided equally between the six trustees. For every additional L.100, a new trustee is to be chosen; so that a trustee can only risk his proportion of L.100. None but the labouring classes are admitted to this benefit; and there is no restriction as to place of residence."

"OBSERVATIONS.

"These few simple rules are all that have hitherto been found necessary for the establishment of this charity, the design of which is both original and useful. To those who have applied themselves to that branch of political economy which relates to increasing the comforts, and improving the morals of the inferior classes of society, it must be obvious that every endeavour to encourage and enable them to provide for their own wants, rather than to rely upon the gratuitous gifts of the rich, are of great advantage to the whole community.

"It is not sufficient to stimulate the poor to industry, unless they can be persuaded to adopt habits of frugality. This is evinced amongst many different kinds of artisans and labourers, who earn large wages, but do not in general possess any better resources in the day of calamity than those who do not gain above half as much money. The season of plenty should then provide for the season of want, and the gains of summer be laid by for the rigours of winter. But it must be obvious how difficult it is for even the sober labourer to save up his money, when it is at hand to supply the wants that occur in his family. For those of intemperate habits, ready money is a very strong temptation to the indulgence of those pernicious propensities.

"Many would try to make a little hoard for sickness or old age, but they know not where to place it without danger or inconvenience. They do not understand how to put money in, or to take it out of the bank; nor will it answer for small sums, either in point of trouble or of loss of time. The same causes frequently occasion thoughtless servants to spend all their wages in youth, and in consequence to pass their old age in a workhouse,—a sad reverse from the indulgence of a gentleman's family, to which they have

Banks for Savings.

been habituated. Many instances indeed have occurred, that, for want of a place of security for their money, the poor have lost their hard earned savings, by lending it to some artful or distressed person, who has persuaded them it will be safe in his hands.

"The success of the little bank for children, connected with the Tottenham Female Benefit Club, mentioned in a former part of the reports, encouraged the present design; and it may be worth remarking, that the bank was opened by an orphan girl of fourteen, who placed L.2 in it, which she had earned in very small sums, and saved in the Benefit Club."

In 1805 and 1806, two pamphlets were published by Mr Bone, in the first of which he seems to have had it chiefly in view to point out the objects to which a scheme for preventing among the poor the miseries of want ought principally to be directed; in the second, to sketch the form of an institution by which those objects might be obtained. The scheme of Mr Bone is, however, nearly as comprehensive as that of Mr Bentham, and, therefore, extending far beyond the subject to which the present article is confined. The following are its principal objects:

1. To provide comfortable dwellings for all who require them.
2. Sums for their maintenance.
3. A provision for widows and children, education for the latter included.
4. Endowments to children at 21 years of age.
5. Temporary dwellings to destitute strangers.
6. To afford small loans.
7. Provision for persons who have belonged to the army or navy.
8. To grant annuities to persons to whom that mode of assistance is the best adapted.
9. To afford a provision for persons lame, or otherwise disabled.
10. To procure situations and employment for those deprived of them.
11. To nurse and educate children, as many as possible of the children of those who are themselves the least qualified for the task.
12. To provide baths and lavatories for the poor.

To the accomplishment of this scheme, banking, however, contributes a diminutive part. It is not proposed that all this should be accomplished by the funds of the poor themselves. The receipt, however, of the contributions of the poor, forms an essential article of the plan, and so far it involves in it the principle of a savings bank. It was proposed to receive the contributions of single persons, and return them with premiums at the period of marriage; to receive, farther, the contributions both of the single and the married, with a view to the future and ultimate provision; for though all persons would, according to this scheme, receive a provision, it would be a provision with more or less of excellence, according to the contributions of the individual.

Savings Banks in Scotland.

In 1807, the minister of the parish of West Calder, in Scotland, founded a bank for the savings of the principal class of his parishioners; and in 1810, without any knowledge of what had been accomplished in West Calder, Mr Duncan, the minister of Ruthwell, another of the Scottish parishes, established one in his own, in nearly a similar form. Mr Duncan, in a well written pamphlet, in which he describes the form of his own institution, and explains the object which the system has in view, and the principles upon which it is founded, informs us, that his idea of an economical bank for the savings of the industrious, was accidentally suggested to him by a perusal of the pamphlet, entitled, *Tranquillity*, of Mr Bone, at a time when his mind was peculiarly excited to the consideration of the subject, by the circumstances of the poor in the town and vicinity of Dumfries, and by the threatened approach of what he deemed a national misfortune, the introduction of poor-rates.

The course pursued by Mr Duncan is in the highest degree instructive. It is founded upon an accurate knowledge of human nature, in which the men who step forth from elevated situations to ameliorate the condition of their fellow-creatures, are in general singularly deficient, and therefore most commonly reap nothing but the natural fruit of injudicious measures—disappointment. As a great effect was intended to be produced upon the minds of the people, Mr Duncan saw the necessity of carrying the minds of the people along with him, and of adopting the most powerful means for making them feel and take an interest in the concern. Unless the interest is felt, and powerfully felt, the operation of the machinery will be feeble, and its effects trifling. Novelty may give it some appearance of strength for a time, but this will gradually decay.

In the first place, it was necessary that every cause of obstruction should be removed. "The prejudices of the people should be carefully consulted; they should be treated even with delicacy; and the most unreasonable scruples of the ignorant and suspicious should, as far as possible, be obviated." It is not duly considered by the upper ranks of the population, how inseparable from human nature are the suspicions of those who are weak, toward those who are strong; the suspicions of those who are liable to be hurt, toward those who are capable of hurting them. And it is only the blindness of self-love, and our inattention to evils in which we are not called to participate, that leave us ignorant of the actual grounds in practice, whence, even in this country, the institutions of which are so much more favourable than those of most other countries to the poor, the weak have reason to dread the interference of the strong.

So much for removing the causes of dislike. More is necessary to create a positive, and still more to raise an ardent attachment. The springs of human nature must be skilfully touched. Mr Duncan knew where to find them, and he looked to the means which the circumstances of the case afforded for placing them in action. "It may be observed in general," he says, "that in all those situations, where it is practicable to assimilate the mode of management to the scheme of Friendly Societies, the advantage to be derived from such a circumstance ought not to be overlooked." If there were nothing in the case but the actual existence of these societies, and the favour with which the people regard them, the importance of this advice would still be more than considerable. But, says Mr Duncan, "On this subject, it may be proper to attend to the following

remarks: Those who are at all acquainted with the history of friendly societies, must be aware, that they owe much of their popularity to the interest excited among the lower orders, by the share to which each of the members is admitted in the management of the institution. The love of power is inherent in the human mind, and the constitution of friendly societies is calculated to gratify this natural feeling. The members find, in the exercise of their functions, a certain increase of personal consequence, which interests their self-love in the prosperity of the establishment. Besides, by thus having constantly before their eyes the operation of the scheme, in all its details, they are more forcibly reminded of its advantages; and not only induced to make greater efforts themselves for obtaining these advantages, but also to persuade others to follow their example. Hence it happens, that a great number of active and zealous supporters of the institution are always to be found amongst the members of a friendly society, who do more for the success of the establishment than can possibly be effected by the benevolent exertions of individuals in a higher station."

For these reasons Mr Duncan held it expedient to give the contributors themselves a share in the management of the institution; and that share was well chosen. The contributors in a body were not fit to be the acting parties; but they were fit to choose those who should act for them. A general meeting is held once a-year, consisting of all the members who have made payments for six months, and whose deposits amount to L.1. By this meeting are chosen the court of directors, the committee, the treasurer, and the trustee, the functionaries to whom the executive operations are confined. And by this also are reviewed and controlled the transactions of the past year, with power to reverse the decisions of the committee and court of directors; to make new laws and regulations, or alter those already made; and, in other respects, to provide for the welfare of the institution.

The power of choice is somewhat limited by the qualifications required. The society consists of two sorts of members, the ordinary, and the extraordinary, and honorary. The general meetings have alone the power of electing honorary members; but the Bank Trustee, the Lord-Lieutenant and Vice-Lieutenant of the county, the Sheriff-depute and his substitute, the members of Parliament for the county and burgh, the ministers of the parish, with certain magistrates of the town, are honorary members *ex officio;* and there are certain regulated subscriptions or donations, of no great amount, which constitute the person paying them, *ipso facto*, an extraordinary or honorary member. Now, it is from this list of honorary and extraordinary members that the choice of functionaries by the general meeting is annually to be made, provided a sufficient number of them should be disposed to accept of the offices designed; if not, from such of the ordinary members as make deposits to the amount of not less than L.2, 12s. in the year.

It is not fitting here to enter into the details of the organization, or those of the executive arrangement. It is sufficient to state, that deposits are received in sums of 1s., bear interest at the amount of L.1; and are always payable, with compound interest, on a week's notice.

It seems not to have been till 1814 that the project of savings banks made any farther progress in Scotland. In that year, "the Edinburgh Bank for Savings was instituted," says Mr Duncan, "by a society of gentlemen, of the first influence and respectability; who, from their enlightened labours in the suppression of mendicity, and in the establishment of a permanent provision for the poor, had already acquired no trifling claim to the confidence and affection of the public, and particularly of the lower orders." In the constitution of this bank, the interference was rejected of the depositers themselves; who were simply required to confide their money in the hands of the gentlemen who undertook the management of the institution. "This circumstance," says Mr Duncan, "has operated as a powerful obstruction to the success of the plan. The truth of this will appear in a very striking point of view, if we contrast the progress of the scheme in Edinburgh with that of the Ruthwell parish bank, or of those institutions which are formed on a similar plan." And he then presents a statement of facts, which fully support the position, and strongly illustrate the importance of the principle on which the Ruthwell institution was founded.

Mr Duncan, from deference to the gentlemen who made the decision for the Edinburgh bank, seems willing to allow that a general meeting of all the contributors, and a reservation to that meeting of certain appropriate powers, useful and important as it is, may, in great cities, such as Edinburgh, be attended with inconveniences which outweigh its advantages. May not this, however, be a concession too easily made? It would, at least, be desirable to have good reasons presented for the sacrifice of so great an advantage, before we consent to its being made. There is an obvious inconvenience in assemblages of people, of any description, when too large. And if one bank were to serve for the whole of a great city, and the contributors should amount to any considerable part of the population, the assemblage would undoubtedly be too large. But this, under the circumstances in contemplation, would not be the case. To accommodate the customers, there ought to be a bank in every parish, or similar district. There would be no greater inconvenience in calling together the moderate number of contributors to such a bank in a city, than in the country. The fact is proved by the ample experience of friendly societies; the members of which do actually meet much oftener than once a-year, and devoid of many advantages which the mixture of persons of the upper classes would afford to the association of a savings bank. If any central, or general institution, to give unity and combination to the operations of the different banks of a great city, were found to be useful, it might be formed of delegates chosen by the committees of the several district or parochial banks; and thus, without any inconvenience that can be rationally contemplated, all that fervent interest which is the natural effect of giving the contributors themselves a part to act in the formation and conduct of savings banks, would be provided for and secured. In London itself,

Banks for Savings.

there are various institutions, wholly dependent upon voluntary contributions, the subscribers to which, though extremely numerous, are annually called together for the election of committees and other managers. The society of *Schools for All* may be adduced as a conspicuous example. And where is the inconvenience that is ever found to result?

Savings Banks in England.

In the meantime, efforts were begun for the extension of the system in England. In the year 1813, a judicious and successful attempt was made by Dr Haygarth for the establishment of a bank for savings at Bath, where, sometime before, an institution, under the name of a servant's fund, had been formed on nearly similar principles, at the suggestion of Lady Isabella Douglas, sister of the Earl of Selkirk.

The circumstances of England were in several respects much less favourable to any plan founded upon the savings of the poor than those of Scotland. The disadvantages existing in England are justly enumerated by Mr Duncan, under four heads; 1st, The character and habits of the people; 2dly, The nature of the ecclesiastical establishment; 3dly, The system of poor laws; 4thly, The state of the banking business.

The first three are general, and the nature of the obstruction which they afford in some degree obvious. The illustration of these here may therefore be waved. The last, however, so intimately concerns the operations of the banks for the poor, that it requires a difference even in their constitution. It is the practice of the banks of Scotland to allow interest for the monies deposited with them; and so perfect is the foundation on which some of them are placed, that the security attached to the deposits they receive, is equal to that of the Bank of England itself. The operations of the economical bank are here, therefore, simple in the highest degree. It has only to open an account with one of these banks, and pay to the contributors the interest received, making such a deduction as the expences of the institution may require.

In England it is not customary for banks to allow interest on the deposits which are made with them. And where possibly interest might be obtained, the security would not always be good. The savings banks have no source whence interest can be derived with the due measure of security, except the public funds. But, with respect to them, a great inconvenience arises from the fluctuation of price. What is desirable, above all things, is such a degree of simplicity and plainness in the transactions, that the reasons of every thing may be visible to the uninstructed minds of the people with whom the institution has to deal. But this fluctuation in the price of stock is an unavoidable source of complication and obscurity. The money of one man produces more, that of another less, according to the price of stock, at the time when his deposit is made. When it is withdrawn, a sum is received, greater or less than that which was put in, according as the price of stock has risen or declined.

The plan upon which Dr Haygarth proceeded, in the bank which his strenuous exertions were the means of setting on foot in Bath, was to make every depositer, to the value of one or more pounds of stock, a proprietor of stock to that amount, and entitle him to receive his dividends every six months, the same as those paid at the Bank of England, one sixth being deducted for the expences of the institution. In the constitution of this bank, no part of the management, and no control over it, were given to the depositers. Certain trustees and managers were constituted, with powers of supplying vacancies; and the money of the depositers was vested in the funds in the names of a certain portion of the trustees.

Banks for Savings.

In the month of November 1815, a bank was projected for the town and vicinity of Southampton, to which the zeal and influence of the Right Honourable George Rose in a great degree contributed. In the formation of this institution, the model of the Edinburgh bank was principally followed. It was composed of a certain number of noblemen and gentlemen, who formed themselves into an association for banking the money of the poor; excluding entirely the intervention of the depositers. It differed from the bank established at Bath, which gave the depositers a proportion of the dividends, and left them to the chance of gain or loss by the fluctuation of the stock which their money had purchased; the Southampton bank, though it vested the money in government securities, undertook to pay a fixed invariable interest of 4 *per cent.* on each sum of 12s. 6d.; and to repay the deposit when demanded, without addition or diminution. The chance of any rise or fall in the price of the funds, the bank, in this way, took upon itself. The Southampton, like the Edinburgh bank, limited the amount of deposits which it would receive from any one individual; and fixed the sum at L. 25.

Some attempts were also made in London. A bank was instituted, under the influence of Barber Beaumont, Esq. in the parish of Covent-Garden. A committee of the inhabitants of the parish, rated at L. 50 and upwards, together with the members of the vestry, form one committee, and twenty-four of the depositers, chosen by themselves, form another committee, who jointly choose their agents, and conduct the business. The want of security in this plan is an obvious objection; the money remaining in the hands of certain individuals, in the character of treasurers, allowing interest at 5 *per cent.*

A bank was opened in Clerkenwell, another parish in the metropolis, on the 29th of January 1816, chiefly through the instrumentality of Charles Taylor, Esq., on a plan by which the depositers appoint their directors, their committees of accounts, their superintendents, &c. from their own number, and thus conduct the business of the institution wholly for themselves. The treasurer is allowed to retain to the amount of only L. 200, for which he gives security, and allows interest at 5 *per cent.* for the sum in his hands. The other funds are invested in government securities. The great defect in this otherwise admirably constituted institution, seems to be the limiting the choice of managers and functionaries to the depositers themselves. Why should the depositers deprive themselves of the advantage of choosing a person who would be eminently useful as a manager, though not of a rank of life to require the institution for his own use? If the depositers have the power of choosing, for the management, whom they

please, depositers or not, they will have all that share of action which is necessary to establish their confidence and animate their zeal; while, at the same time, men of superior education and influence may be joined with them, and prevent, by their wisdom and authority, any error to which the business might be otherwise exposed. As often as men of superior education and fortune showed a disposition to render themselves useful in the conduct of the institution, daily and universal experience prove how certainly and gladly they would be chosen. In the meantime, the prosperity of the Clerkenwell bank is a complete proof of the safety with which that co-operation of the contributors, the utility of which is so well demonstrated by Mr Duncan, may be employed in the greatest cities. Clerkenwell is a parish, a great part of which is inhabited by some of the poorest people in the metropolis; the establishment of the bank was attended with nothing which was calculated to excite any attention; with advertisement scantily sufficient to make it known in the district; yet on the 22d of April, less than three months after the time of its institution, it had 157 depositers, and had received L. 269, 11s. 6d.

These local and confined attempts in the metropolis were followed by others on a larger scale. *The Society for Bettering the Condition of the Poor* took measures for interesting a sufficient number of noblemen and gentlemen to establish a grand Savings Bank, or Provident Institution, which was deemed a preferable name, for the whole of the western half of the metropolis. Several meetings of persons of high rank and others were held during the month of March 1816. The plan of the bank of Southampton, to pay a certain fixed rate of interest, and return the neat deposit on demand, was first proposed. This, with regard to the facility of giving satisfaction to the contributors, and avoiding all misconception on their part, injurious to the prosperity of the institution, was highly desirable. But, after a due consideration of the danger to which the institution would, on this plan, be exposed, in the event of any great depression of the price of stock, it was resolved to follow the example of Bath; to render each depositer a stockholder, and consequently himself liable to either the profit or the loss which the fluctuation of stock might occasion. This institution was composed of the noblemen and gentlemen by whom it was promoted, who formed themselves into an association, consisting of a president, vice-president, trustees, and managers; wholly excluding the co-operation of the depositers, and all intervention or control on their part. This institution was opened in Panton Street, Hay Market, on the 15th of April following; and another, promoted by the principal gentlemen in the city, and founded on similar principles, was soon afterwards opened in Bishopsgate Street, for the eastern half of the metropolis.

Of the bank for the western division of the metropolis, a particular account has been published by Joseph Hume, Esq. one of the managers, which deserves attention, as containing a valuable set of practical rules for the detail of the business, according to the principles on which that institution is founded; and, above all, as containing the description of a system of Book-Keeping, admirably adapted to the purpose of savings banks in general, and of which that gentleman himself was the principal contriver.

By Mr Hume and Dr Haygarth, we see that the term *Provident Institution* is applied as the name of those associations which have it for their object to enable the poor to place their money in the stocks. The term Bank, whether called a Savings Bank or a Frugality Bank, they would confine to these institutions which pay a fixed interest, and return the neat deposit. The term Bank, however, is equally applicable to both, and the best denomination they can receive. Some adjunct is wanted to distinguish this from other species of banks, and no good one has yet been found. Neither *Frugality* nor *Savings* is distinctive; every bank is a frugality bank. *Poor's Bank* would be the best, but for one conclusive objection, that it is humiliating, and in common acceptation disparaging.

As government securities afford in England the only expedient, attended with safety, for employing the deposits of the poor; but as these securities are, at the same time, attended with the great inconvenience of fluctuation, and require the transmission of the money to and from the metropolis, of which the inconvenience would often be considerable; Mr Hume is of opinion, that the powers of government should be employed for the removal of these two inconveniences, which would merely afford to banks for the poor in England those advantages which they already enjoy in Scotland, from the admirable state of the banking business. The effects might be accomplished by the payment of the money to the receiver of each county, and by the receipt from him of the proper returns. This would no otherwise change the nature of the transaction, than that the money would thus be lent to government in a way extremely convenient to the poor, while, by purchase into the public stocks, it is still lent to government, but in a way far from convenient to that class of the people.

There may be, and there are, solid objections to the rendering any great portion of the people the creditors of government, as being unfavourable to that independence of the people on the government, on which all security for good government depends; but if the people are to be rendered the creditors of government, there can be no objection to them being rendered so in a way convenient to themselves, rather than in a way which is the contrary. And if there is no other security but that of government to which the banks for the poor can have recourse, we are reduced to the alternative of either having no banks for the poor at all, or lending the money to government. It will occur to some persons, that it might be lent to the parishes on the security of the poor-rate. But to those who contemplate the abolition of the poor-rate, this will not appear desirable as a permanent expedient. If counties were managed according to their ancient constitution, the best plan might be, to lend it to the counties, on the security of the county rate. But even in this case, it could not be lent without admitting a prodigious evil, the principle of county debts.

No mention has been made of the plan of Mr Baron Mazeres, in the account which has been ren-

Banks for Savings ‖ Bannockburn.

dered of the successive steps by which the business of savings banks has been brought to its present state; because it was not conceived that this plan corresponded to the idea of a savings bank. It is, however, necessary to be described, because it is not impossible that some of the ideas realized in savings banks may have been derived from it. The plan of Baron Mazeres was a proposal for establishing life-annuities in parishes, for the benefit of the industrious poor. It was published in 1772, accompanied with the suggestion of certain alterations by the celebrated Dr Price. It was recommended to the nation to obtain a law, for enabling the parish officers in England to grant, upon purchase, to the labouring inhabitants life-annuities, to be paid out of the parish rates. The measure met with support from some of the most distinguished characters of the time, and a bill was brought into the House of Commons by Mr Dowdswell, under the auspices of Mr Burke, Sir G. Savile, Lord John Cavendish, Mr Dunning, Mr Thomas Townshend, and others, for carrying it into effect. The plan received the sanction of the Commons, the bill was passed, and carried to the House of Lords. Here it was not equally fortunate; it was not even permitted to come to a second reading. One cannot conceive any very good reason for throwing it out; because, if it produced any effects, they could not be evil. The defect of the project appears to consist in this, that it was not calculated to produce effects at all; it involved in itself an obstruction fatal to its operations. To purchase these annuities a sum of money, large to the purchaser, was demanded all at once. How was he to possess it? Whence was he to obtain it? The means were almost universally wanting, and likely to continue so.

It is worth while to mention, that a savings bank, entitled *Le Bureau d'Economie*, was established by law at Paris, in one of the first years of the French revolution, and it was in existence till a late period, perhaps is to the present. The account of it which we have seen, is in the *Archives of Useful Knowledge*, published in Philadelphia, where a bank of industry was lately established. Mr Bentham's plan of a frugality bank, added to this scheme two important amendments, which at once brought it within the range of practicability, and enlarged the bounds of its usefulness. He proposed that the people should purchase life-annuities, by sums deposited gradually; and that these annuities should be convertible into other forms of benefit, suitable to the exigencies of each individual.

General Rules for the formation of these Banks.

With regard to the best model of a savings bank, there is nothing of much importance which remains to be said. The great difficulty consisted in the original idea. When that was fully framed, every thing else suggested itself, without the smallest difficulty. Two things were immediately seen to be fundamental: In the first place, security for the funds: In the second place, the zeal of the people. The best general instruction which can be given to those who have institutions to form, is to set these two objects before them, as the ends which they have to pursue; and to adopt the means, which, in the peculiar circumstances of each case, promise to be most effectual in attaining them. 1. With regard to security, the course appears to be abundantly plain. There is perfect security with many other advantages in the great banks in Scotland, which of course should be universally employed. In England, there is no resource but government security, to which, as at present existing, several inconveniences are attached. 2. With regard to the excitation of that degree of fervent interest among the people, which is necessary for the production of any considerable effects, all persons will not have their minds equally open to conviction. Yet the means appear to be abundantly certain and clear; let the contributors, in annual meetings, choose their own office-bearers, not limiting the choice to their own body; and let the people of weight and character in the district, not only show their readiness, but their desire to be chosen. This is the general idea; it may be modified into a variety of forms, according to the circumstances of different places; circumstances to which matters of detail ought as much as possible to conform. It is an appendage to this principle, that the numbers, hence the district, should not be large, which a single bank is destined to serve. This appears to be expedient, or rather indispensable, on other accounts; to facilitate access to the customer; to prevent loss of time by attendance, if numbers should be liable to repair to the same office at the same time; and to render practicable, by division, the otherwise impracticable amount of labour, which, if the great majority of the people should bring deposits, the management of them will create. (FF.)

BANNOCKBURN, a rivulet in the county of Stirling, celebrated for a battle fought on its banks in the earlier part of the fourteenth century. As no correct details of this battle have been given in the body of the work, it becomes necessary to supply that defect in this place.

The failure of the royal line of Scotland, by direct descent, in the grand-daughter of Alexander III. who died in the year 1290, excited a competition among several powerful nobles for the crown. But deciding their respective rights by the sword would have deluged the kingdom with blood; nor were the finances of any in that condition which could enable them to maintain an arduous and protracted contest. The claims of all were, therefore, by common consent, submitted to Edward I. of England, a warlike and politic prince, who, having heard them patiently, with due solemnity adjudged the throne to John Baliol. Edward, though without apparent partiality, had not lost sight of his own interest; but the truth was soon betrayed, that he wished to render Scotland an appanage of England, could it have been effected. The right of superiority was asserted, acknowledged, and then resisted; but Edward had power in his hands, and the abdication of Baliol followed a short and troubled reign. That monarch now openly avowed his design of subjugating Scotland, which he affected to consider only as a fief of his kingdom. Some patriots arose in the course of an interregnum; but their co-operation being generally disturbed by jealousies among

themselves, they were quickly overwhelmed, and a large proportion of the peers and barons swore fealty to the English sovereign. By a barbarous sentence, the most distinguished defender of Scottish liberty, Sir William Wallace, was put to death at London, and Edward conceived that the terror of his punishment would restrain others from resistance. He was mistaken, however, for Robert Bruce, Earl of Carrick, grandson of one of the original competitors for the kingdom, reviving his claim, was crowned at Scone in the year 1306, and prepared to vindicate it by the sword. He was at first unsuccessful, and two of his brothers perished in the contest, while the English were repeatedly victorious, and obtained possession of all the strong-holds throughout the country. Meantime, after expressing irreconcilable hatred to Bruce, Edward died, and his son, who solemnly swore that he never would remain two nights in the same place until he reached Scotland, resolved to maintain his superiority. But the imbecility which he speedily displayed, his ignorance of the real dispositions of the people with whom he had to deal, and other circumstances, induced many who had pledged their fealty to his father now to desert himself; and the partizans of Bruce, who was generally acknowledged the real and legitimate sovereign, rapidly increased in number. The south and west were released from the power of the English; several places of strength were gained, either by force or stratagem; and, encouraged by success, he even ventured to penetrate the less protected parts of the neighbouring kingdom. Edward, however, sought to preserve the allegiance of those who still adhered to his interest, by conferring obligations upon them; and as there were many in Scotland disaffected to the government of Bruce, he never abandoned the original plan of subjugation. After various successes and discomfitures on either side, one of the strongest fortresses, Stirling Castle, then in possession of the English, was invested by Edward Bruce, a surviving brother of the king. The governor, Sir Philip Mowbray, pressed on all hands, offered to surrender if he should not be relieved by his countrymen on the 24th of June 1314, to which Bruce, commanding the besiegers, incautiously assented; and although he thus incurred the displeasure of his brother, the sanction of the latter was not withheld. It was these preliminary events, which we deem it necessary to explain, that were productive of the celebrated battle of Bannockburn.

Edward being made acquainted with the circumstances, quickly ascertained the importance of carrying succours to Stirling Castle, and resolved to levy a powerful force for the purpose of combating the Scottish king, who was posted so as to intercept his access to it. From the writ commanding the different counties to furnish their respective proportions of the military, it would appear either that the design of Robert to dislodge his enemies was long premeditated, or that he had remained a considerable time encamped at the place of rendezvous, the Torwood, a few miles east of Stirling. It specifies that "the Scots had endeavoured, as far as they were able, to collect a vast body of foot in a strong and rugged position, where it was difficult for cavalry to act, between him and his castle of Stirling." Probably the Torwood then extended farther west than we are accustomed to fix its limits at the present day; therefore we must seek for the Scottish camp nearer the object of contention. There were assembled about 30,000 men, besides an unarmed and undisciplined rabble of followers and retainers, amounting to a great number, not less than perhaps two-thirds of the regular force. The Scottish historians calculate the English army at 100,000 men.

But here we cannot sufficiently regret that it is principally from a poetical narrative and tradition we are enabled to deduce the interesting events of that æra; therefore, as poets are in general but faithless historians, their writings must always be received with reserve. At the same time, Barbour, the poet who records the battle of Bannockburn in detail, seems to have had little in view, besides the glory of his country; and there are also some slight notices to be found elsewhere corroborative of the general train of the history.

On Saturday the 22d of June, Robert having received intelligence that the English had reached Edinburgh, withdrew his army from its encampment in the Torwood, to take up another position in the neighbourhood of Stirling Castle. There he extended his troops in three divisions, occupying a wood, it would appear, from the stream called Bannock, on the right towards the church of St Ninian, and on the left nearly, it is supposed, in the direction of the present road from Edinburgh to Stirling. In the night he directed a great number of small pits to be dug knee-deep, and covered with turf, concealing at the bottom a kind of projecting spikes called calthrops, or caltrops, designed for the destruction of cavalry. The position was besides protected by a morass in the vicinity, and peculiarly favourable, in many respects, against the attack of cavalry, which the Scottish king chiefly dreaded. On Sunday the 23d, an alarm spread of the approach of the enemy, and Bruce prepared to receive them, for he had now chosen the ground on which he awaited the attack; his whole army heard mass, and in answer to his proclaiming that those who were not confident of victory might retire, all unanimously declared their resolution to conquer or die. His troops were marshalled in three divisions, of which that on the right was commanded by his brother Edward, the left wing by Lord Douglas and the young Stewart of Scotland, and the centre by his nephew, Randolph, Earl of Murray, while he himself took the command of the reserve, posted on a rising ground in the rear, whence he could obtain a view of the passing incidents. But it is remarkable that this reserve consisted of the most savage part of the inhabitants of Scotland, the Western Islanders and men of Argyle, as also his own vassals of Carrick in Ayrshire. The followers of the camp were now sent to a valley at a little distance to the left of the position. In this manner Bruce designed to deceive his enemies.

Meantime a squadron of 800 horse was detached from the English army for the purpose of gaining Stirling Castle, by a circuitous route through the low ground to the north-east. The king, the first to perceive it, reproached the Earl of Murray, his nephew, with leaving the place exposed, and he,

Bannock-burn. anxious to repair his fault, hastened with 500 spearmen to check the enemy, wherein he with difficulty succeeded. Soon after, the van of the English appeared in sight, while Robert was in front of the Scottish line. He was recognised by Henry de Bohun advancing a bow-shot before his comrades, from a crown surmounting his helmet, and the authoritative manner in which he disposed his troops. Being mounted on a sorry horse, the Englishman quickly advanced upon him, but his spear missing the king in his course, the latter, rising in his stirrups, cleft his helmet with a single blow of his battle-axe, and Bohun fell to the earth. This valiant deed encouraged his people; but to his friends, who warned him he had exposed himself too hardily to danger, he tacitly seemed conscious of temerity, and regretted that the shaft of his weapon had been broken by the violence of the blow. This closed the operations of the first day.

The armies reposed in the vicinity of each other; both were impatient for the succeeding dawn, the one anticipating undoubted victory, the other in anxious hopes of being liberated from the yoke of strangers. Bruce addressed his troops, recapitulating the conduct of the enemy, how the government of the country had been usurped, and those that had fallen into their hands most barbarously treated; that now they were to fight for all they held dear, their own personal liberty and the safety of their families. He showed them, that their position was such as would insure success; that they fought in a good cause, but the English only for conquest; that they would, when victorious, be enriched with the spoils of the vanquished, and he promised that the heirs of those who fell should enjoy privileges merited by the conduct of their predecessors. But he strenuously urged the necessity for order, to avoid pillaging the slain, and to preserve their line unbroken.

At break of day, the Scots, drawn out in battle array, beheld the English already prepared; but, notwithstanding their own inferiority of number, they were animated by the justice of their cause, and with confidence in their leader. To propitiate the Deity, Maurice, Abbot of Inchaffray, celebrated mass, and passed in front of the army, bearing a crucifix in his hand, and exhorting the soldiers. The troops then partook of some refreshment, and Bruce, in conformity with the customs of his æra, created some of his most distinguished followers knights.

The English army was commanded by Edward in person, attended by a body guard of 500 cavalry well armed; and among his troops were 52,000 archers. But the same unanimity did not subsist as among his foes; although he, on his part, was confident of victory; and the Scottish host having knelt with one accord to utter a pious ejaculation, and receive benediction, he exclaimed to those around him, "Behold, they kneel to ask mercy!" He was quickly undeceived.

A signal was now given; the armies approached, and a sanguinary contest ensued, unexampled in the annals of British history. The van of the English, composed of cavalry, galloped on to charge the right wing of the Scots, commanded by Edward Bruce, which received them with intrepidity. While this wing was engaged, Randolph advanced with a division to meet the main body of the enemy; and the left wing also hastened to participate in the conflict. Repeated charges of cavalry attempted, but in vain, to break the Scottish line; it proved impenetrable; they were everywhere resisted and repulsed. At this time, the battle seems to have been general, but the Scots were drawn up in a small and compact form, while the unwieldy mass of the English army could only be partially brought into action. Nevertheless, the former were grievously annoyed by the archers; but they fought desperately with their spears, swords, and knives, and also iron clubs or maces; besides, they were protected by light armour, which did not restrain their agility. Edward, the king's brother, was hard pressed by the English cavalry, and the Earl of Murray, making a movement to his support, was almost overwhelmed by the multitude of the enemy, while a terrible shower of arrows saluted the third division advancing to their relief, which galled them severely. The English still presented a vast and extensive front, but the king directed one of his chosen leaders, Sir Robert Keith, to take the archers in flank with 500 horse, and their impetuosity proved irresistible. They were suddenly overthrown, and fled with precipitation. The king, satisfied with this important advantage, brought up the reserve, encouraging his people to press onward, as they were now sure of victory; and he spoke with greater confidence, as the Earl of Gloucester, in endeavouring to rally the fugitives, was unhorsed and slain. The reserve about this period fell into the line, which had been weakened in no inconsiderable degree by the previous operations: the Scottish archers, in their turn, did uncommon execution among the enemy; they inspirited each other to the attack, and their comrades bore every thing down before them. The numbers of the English proved their own destruction: for those who recoiled, threw the rest into disorder, and those who fell were immediately trampled to death and destroyed. Notwithstanding, the battle continued to rage furiously, and victory was long and keenly contested. But, at length, at this critical period, the retainers of the Scottish camp, who had previously been sent to a valley in the rear, suddenly appeared on the neighbouring height in view of the English army. Intimidated by the approach of what was believed a strong reinforcement, they soon began to waver, and as Robert urged his troops forward, they gradually receded, and at last took to flight. Edward, with 500 horse, prepared to seek shelter in Stirling Castle, but the governor found means to dissuade him from it; and he then consulted the speediest means of escape. The rout of his army became complete, their bands were totally broken, and they fled with precipitation on every side. Some sought refuge among the rocks of the castle; many hurried to the river Forth, where they were drowned; but the most terrific scene of carnage was in the valley where the rivulet Bannock flows; for the ascent towards the east being steep and difficult, and then probably impeded by wood, they were exposed to inevitable destruction. Scarce any who took that direction escaped; the course of the stream was interrupted, and a bridge was formed of the bodies of

the slain. The peasantry, witnessing the defeat of the English soldiers, inhumanly slaughtered them, gratifying their revenge, and glutting themselves in blood. Nevertheless, prodigies of valour were performed; and, at the earlier part of the rout, Sir Giles Argentine telling Edward it was not his custom to retreat, rushed amidst his enemies and was slain. But Edward, hotly pursued, continued his flight, followed by 60 horse under command of Douglas, until both, as if by mutual consent, halted at Winchburgh, 20 miles from the field of battle. Again mounting, the pursuit was continued 40 miles farther to Dunbar, where the castle gates being opened to Edward, a vessel conveyed him to England.

Meantime, the scattered fugitives were either falling under the sword of their enemies, or seeking safety in the speed of their flight. A body of Welshmen appeared nearly naked, having been induced to throw aside their upper garments, in order to fight with the greater freedom; and now were the easiest victims. Some continued to conceal themselves in the woody parts of the neighbourhood in hopes of mercy; and Sir Marmaduke Twenge, after lurking through the night in a bush, surrendered himself to Robert, personally, by whom he was courteously treated.

There are two things which it is equally difficult to ascertain, the numbers who fell, and the duration of the engagement. The victors are always prone to magnify their conquest; the vanquished to diminish their defeat, and to exaggerate its difficulty. If it be true that Edward fled on the same day to Dunbar, the conflict, though from dawn, could not be very long; yet, it is not easy to conceive how the unwieldy mass of the English army could be brought into action unless by slow operations. The loss on both sides was certainly very great. Barbour asserts that of the English to have been 30,000 men, and that 200 knights were killed. But the truth of this calculation is disputable, especially as it is said elsewhere, that only 42 knights were slain, and 60 made prisoners. Barbour also affirms, that only two Scotsmen of note fell on the occasion, Sir William Vipont and Sir Walter Ross. The king bitterly regretted the Earl of Gloucester, for he was his own near relative, and historians maintain, that had the Scots known him he would not have fallen that day. He caused his body to be carried to St Ninian's church, and watched all night, and then sent with that of Lord Clifford to England. The more distinguished slain received interment in consecrated ground, the others were thrown into pits. The booty taken in the battle was immense; so great, indeed, as to disseminate riches throughout the kingdom, which may well be believed, as the English anticipated nothing less than discomfiture. "O day of vengeance and fatality," one of their historians exclaims, "hateful accursed day, to be blotted from the circle of the year; a day which tarnished the glory of England, despoiled our nation, and enriched its enemies to the amount of L.200,000. How many valiant youths and illustrious nobles, how many excellent horses and beautiful arms, how many precious vestments and golden vessels, were lost in that single unfortunate day!" The privy-seal of Edward was also among the spoils, but restored by Robert, who used his victory with such clemency and moderation, as to gain the applauses even of the hostile nation. Among the prisoners was Baston, a Carmelite friar, said to have been brought by Edward to celebrate his expected conquest; he now obtained his freedom on condition of paying a similar ransom, but in favour of his enemies. His poem probably merits more attention and confidence than ought to be bestowed on any other narrative of the battle, because he alone was contemporary with it, and most probably was a spectator of many of the incidents which happened twenty years before Barbour was born. But we must again regret that it fell to the share of poets only to perpetuate the remembrance of events so important and interesting.

The immediate consequences of this great victory were the surrender of all the fortresses of Scotland to their lawful owners, the liberation of the inhabitants from a foreign yoke, and the firm establishment of the sovereign on the throne. Many inconsiderable engagements have been magnified into battles, but this may probably vie with those most celebrated in history, though fought at a period when the nation was, without all doubt, almost in a savage state. Some memorials of it still remain on the spot; armour and weapons have been frequently dug up from the neighbourhood; and at an interval of 500 years, the inhabitants of the vicinity met on the 24th of June 1814, to celebrate the triumph of their ancestors, the memory of which has been sedulously preserved among them. (s.)

BARBARY STATES.

The name of Barbary, or the Barbary States, is applied by the moderns to an extensive district, occupying, with the exclusion of Egypt, the whole northern coast of Africa. It comprehends also that portion of the western coast which lies to the north of the Great Desert. The States included within this district are entirely independent of, and even hostile to each other; and they also differ in some particulars of their political constitution. There prevails, however, a striking similarity in the whole of their moral and physical circumstances. Throughout all these states, we see the same races inhabiting the towns, the plains, and the mountain districts; the same forms of social life; the same degraded and corrupted barbarism succeeding to ancient grandeur and civilization. Nature presents a corresponding similarity in all the peculiar qualities of aspect, soil, and climate. These resembling features constitute Barbary decidedly one region; and it will, therefore, be convenient to include its various states in one general article.

In the body of the work will be found, under the

Barbary States.

head of **Barbary**, and under those of **Morocco**, **Algiers**, **Tunis**, and **Tripoli**, a pretty copious account of the history of these states, and an outline of their peculiar constitution. It remains to give a general view of the physical aspect of this extensive region, of the various classes of its inhabitants, and of its present political and social condition.

Physical Aspect of Barbary.

Among the natural objects which this region presents, the most prominent is that immense and celebrated mountain chain which, under the name of Atlas, traverses nearly its whole extent. The loftiest portion is that which towers over the plain of Morocco, which, notwithstanding the intense heat of the climate, presents a range of summits clad in perpetual snow. The most recent traveller in this country, known by the name of Ali Bey, states that, after a very careful measurement, he found this portion to be 13,200 feet above the level of the sea. The lower stages are well cultivated, and of luxuriant fertility; while, in ascending, they exhibit every variety of climate, from the torrid to that of the frigid zone. In skirting the kingdoms of Algiers and Tunis, its height is greatly diminished, and is represented by Dr Shaw as not exceeding the loftier eminences of our own island. The greater part of its declivity is here covered with wines and forests; and only occasionally a rocky precipice rears its head above the rest. This part of the range separates into various branches, bearing different names. The most elevated is Mount Jurjura, in the province of Algiers, which is covered with snow during a great part of the year. It forms a species of chain by itself, and rises very high above all others east of Morocco. Besides the grand chain, there is found, between it and the sea, another, called the Little Atlas, extending from the Straits of Gibraltar to Bona in Algiers.

The structure and component parts of this vast range have been very imperfectly explored. It appears probable, however, that, as in other mountain groups of the first magnitude, the central mass, as well as the loftier pinnacles, are composed of granite. Ali Bey states, that the rocks on the coast consist of secondary granite, with sandstone resting on it; a combination which seems deserving of notice, from its resemblance to that which occurs at the southern extremity of Africa. Marble also is said to occur abundantly in the western regions. The lower and eastern branches appear, however, to contain a large proportion of calcareous rocks. The chain, considering its extent, is thought not peculiarly rich in metallic ores, though this character may have been derived from the supine neglect of the inhabitants in exploring its mineral treasures. Silver and copper are procured to a considerable amount in the Tunisian territory. Algiers has lead, and a small proportion of iron. Morocco contains no mines that are known or worked, unless in the province of Suse, the southern extremity of the empire. There, iron is found at Idaultit, and copper, in considerable quantity, in the vicinity of Tessellert. The report of gold and silver mines is treated as a fable by Chenier; but Jackson asserts that he saw evident traces of them in the neighbourhood of Messa. He confirms the report of Leo, that the sovereigns of Morocco discourage the working of these mines, lest the natives, who at present can with difficulty be retained under the yoke, should thus be enabled to set them completely at defiance.

That narrow tract between the Atlas chain and the sea, which comprises the Barbary States, forms a plain of luxuriant fertility, traversed by innumerable streams, descending from this mighty storehouse of waters. Chenier calculates, that upwards of six thousand are poured down from the western Atlas upon the plains of Morocco. The vicinity, however, of the receptacle to their source, prevents their ever forming rivers of great magnitude. The principal are, in Morocco, the Seboo, the Morbeya, the Tensift, and the Suse; in Algiers, the Shelliff; in Tunis, the Mejerdah. The soil, which is naturally of the same loose and sandy character which prevails over northern Africa, is, by this profusion of moisture, rendered equal in fertility to any in the world. Its lightness is even beneficial, by enabling it to be worked with the utmost facility, so that, according to Dr Shaw, a yoke of oxen can plough an acre in the day. But wherever water fails, deserts are produced, which present, on a smaller scale, the same appearances with those immense wastes which extend south of the Atlas. The moisture then, which these mountains supply, is the sole spring of fertility to northern Africa; and Tripoli, where they terminate, borders almost immediately on the sandy waste.

Along the southern base of the Atlas extends a vast region, called Biledulgerid, or more properly Bled-el-Jereede—*the dry country*. It forms a gradual transition from the luxuriant plains of Barbary to the sterile desolation of the Sahara. Large streams, descending from the great chain, traverse it from north to south, till they expand into lakes, or are lost in the sands of the desert. The moisture, evaporated by the scorching winds which blow from the south, is not sufficient for the production of wheat, barley, or the finer fruits; dates are its abundant and almost sole product. They form the food of its inhabitants, and the basis of their commerce. Considered in a political view, this region is nominally subject to those states of Barbary which lie in contact with it; but the subjection scarcely amounts to more than the payment of a certain tribute. The part contiguous to, and dependent upon Morocco, is known by the names of Tafilet and Sigilmessa.

The whole of Barbary abounds, in a very remarkable degree, with different species of saline substances. Common salt particularly is found in every form, and in the greatest abundance. That drawn from the mines of Morocco is of a red colour, very strong and coarse; a white and finer kind is produced by evaporation on the sea coast. The lakes of Barbary are almost all salt, to an equal degree with the sea itself; and in the course of the summer, many of these dry up entirely, leaving the mineral encrusted on their beds. Near the lake of Marks, in the Algerine territory, there is a mountain composed entirely of salt, and all the chains which traverse it contain copious repositories of this mineral. Most of the springs which are not warm are salt; and in the territory of Tunis, there is no fresh water, unless from rain. Many of the rivers, when

Barbary States.

they dry up in summer, leave their banks copiously encrusted with nitrous and saline exudations. Saltpetre is not found in a concrete state; but at Tlemsan, Kairwan, and many other places, the earth is so impregnated with it, that six ounces are obtained from a quintal of soil.

The Atlas mountains, so far as hitherto known, are not the seat of any volcanic eruptions. In East Barbary, earthquakes are frequent during the hot and dry season; they have sometimes thrown down houses, and even carried them to a considerable distance; but these are rare instances; for their effects are by no means so great and terrible as in the south of Europe, and other countries exposed to their ravages. The interior heat, however, manifests itself by that which it communicates to a large proportion of the waters, which flow through this territory. Most of the streams of the Jereede are at least lukewarm; and near Oran, Tlemsan, Gabs, and other places in the territory of Algiers, they acquire a temperature which fits them for warm baths. About 40 miles to the east of Constantina, are those called the Hammam Meskouteen, the heat of which is so intense, as to boil animal food in a quarter of an hour. The rocks over which this rivulet flows are entirely calcined by its influence, which, acting variously on the different substances, consuming some and leaving others nearly entire, produces some curious phenomena. The rocks at one place represent a line of regular cones, believed by the Arabs to be the tents of their ancestors converted into stone. At another place, the action is still deeper and more irregular; the figures of sheep, horses, camels, even of men, women, and children, are presented to the eye, all of which are believed by the natives to have undergone the same transformation.

Vegetable and Animal Productions.

The productions of the soil in Barbary are not materially different from those of southern Europe, the climate being brought, by the vicinity of the mountains, to pretty nearly the same temperature. The grains chiefly cultivated are wheat and barley; of which the crops are abundant, though there is not above one in the year. Oats are not frequent, but beans and lentils are very common. Pease have been introduced by Europeans. Pot herbs and fruits are abundant, and nearly resemble those of Europe, with addition, in the last branch, of the palm tree and the lotus.

The animal world, particularly in its wild members, presents an interesting field of observation. The Numidian lion still retains its ancient character of strength and ferocity. To guard against its attacks, the villages and encampments are surrounded with a species of palisade, and upon the slightest alarm, large fires are kindled; yet these multiplied precautions are not always sufficient to prevent the irruption of this lord of the forests. The animal called here a tiger is in reality only a panther. Wild boars are very numerous, and the hunting of them affords a favourite amusement. The hyæna is common, and is called the *dubbah*. Jackson mentions an animal, called the *aondad*, which inhabits the most lofty and precipitous regions of the Atlas; but, on account of its rugged and inaccessible haunts, has never been sufficiently observed or described. The antelope, or gazel, from its beauty, is the favourite of the Arabs. The Barbary females paint their eyes with a preparation of lead called Elkahol-filelly, in order that they may rival the largeness and blackness of those of the gazel. Gazel here, as angel with us, is the most flattering epithet that can be applied to female beauty. Although the antelope be the swiftest of all animals, he is soon fatigued, so that the greyhound at length comes up with him. The flesh is valued, and is similar to venison. Among the smaller animals, the most noted are the jerboa and jird, which are about the size of a rat, burrow in the ground, and afford agreeable food.

Birds.

Among birds, the chief is the ostrich, an often described species, and which occurs along the whole northern border of the desert. Those about Wedinoon and Cape Bojador are said to be the largest, and to have the finest feathers of any in the world. The feathers form a considerable article in the commerce of Morocco.

Serpents.

The serpent species is very numerous. The great Boa Constrictor is frequently found in the Sahara. It is not poisonous, and destroys merely by its immense strength and ferocity. There are several species, which contain a very active poison; but these, Dr Shaw conceives, do not exist in that great variety which is enumerated by ancient writers. There are also domestic serpents, which are of a more harmless nature, are never molested, and held even in a kind of veneration. The most destructive of this class are the scorpions, which swarm to such a degree, that, in summer, they are often found in the beds. It is believed in Morocco, that the flesh of this animal affords a cure for its bite; and most of the inhabitants, on that account, keep a bottle of scorpions preserved in olive oil. Shaw observes, that those of Algiers and Tunis, to the north of the Atlas, are not very noxious, causing only a slight inflammation and fever, but that, in the Sahara, they are much larger, and their venom more malignant.

Insects.

The insect tribe, in this country, presents a much more terrible enemy, the locust. This destructive insect is bred on the confines of the desert; but at irregular intervals, impelled by some unknown cause, its swarms take their direction towards the cultivated regions. They move in vast bodies, and with an order which resembles that of regular armies. The march is all in one direction, led by a chief, called by the natives Sultan Jeraad. All attempts to stop their course by digging deep pits, or by kindling fires, have proved abortive. The foremost, indeed, fall victims to these means of annoyance; but the vast mass behind, undismayed by the fate of their forerunners, continue to pour on, file after file, in close and uninterrupted succession. The fires are extinguished; the pits are filled up; and the husbandman abandons in despair every attempt to arrest their progress. Every thing green is thoroughly consumed; and the fields, from being clad in all the verdure of spring, assume at once the aspect of wintry desolation. This scourge sometimes continues for several years, and is not unfrequently followed by the still more terrible evil of plague. It forms a very inconsiderable compensa-

Barbary States.

tion to the inhabitants, that they use the locusts as food, and, in that view, regard them even as a delicacy.

Domestic Animals.

The domestic animals do not differ materially from those of Europe, with the exception of the camel, which, though frequent in Barbary, belongs more properly to the desert. The excellence of the horse was formerly the boast of Numidia; and Barbary horses have been highly valued, even in modern times. But the breed is said to have degenerated, chiefly in consequence of the best horses being liable to be seized by persons in power. The ass, and still more the mule, are the animals chiefly employed in labour. The cows are small, and produce little milk. The sheep fed on the Atlas are often of exquisite flavour. The wool being left entirely to nature, is of various quality, some of it coarse, but some very fine. The goats of Morocco produce that species of leather, the softness and pliability of which make it to be held in such high estimation.

Remains of ancient Art.

After surveying the aspect of nature, our attention is next drawn to the ruins of ancient art. The whole extent of Algiers and Tunis, and even deep into the desert, is covered with the most superb monuments of Roman grandeur. Constantina (the ancient Cirta), Spaitla (Suffetula), El Gemme, and many other places, exhibit specimens of the architecture of that people in its highest perfection. The temple at Spaitla is considered by Bruce as the most perfect example of the composite order existing. It seems matter of regret, as well as of surprise, considering the general interest taken in these objects, that the drawings made by Bruce, or under his direction, said to be very fine, should never have been given to the public. The remains of Carthage are entirely subterraneous; yet these still convey an idea of the greatness and industry of that celebrated people. Of that immense aqueduct which conveyed water to the city from the distance of sixty miles, many hundred arches are still to be seen, and several cisterns, nearly entire, are used as habitations by the Arabs. A few years ago, in digging among the ruins of Utica, some labourers found a number of beautiful statues, some mutilated, but others in complete preservation. Among them were two statues of Tiberius and Augustus, the former very finely executed, and four female figures, two of them exquisite specimens of Grecian sculpture. The spirit of antiquarian research seems to be active among the Christian inhabitants of Tunis; and many, even of the poorer classes, are said to be in possession of medals, engraved stones, and other curiosities. These, however, by being dispersed, are in some measure lost to the public. M. Fagan, the British consul at Palermo, lately applied for permission to make excavations, which would no doubt be obtained, provided an adequate pecuniary compensation were offered. In that case, very interesting discoveries would probably be made.

Different Classes of Inhabitants.

The population of the Barbary States is made up of a number of distinct races. A particular survey of each will therefore be necessary, in order to afford any complete view of the subject.

The first and most numerous class are the Moors. This is an European term, derived from the ancient *Mauri*, of whom probably no traces are now to be found. It is applied to the inhabitants of the cities of Barbary, and the country in their immediate vicinity. Their manners and habits of life have been described in considerable detail in the body of the work, under the head of Morocco. Generally speaking, a Mahometan city presents an uniform aspect. Everywhere the same silence and seclusion, the same absence of all gaiety, bustle, and animation; narrow and dirty streets, bordered on each side by lines of dead wall,—each individual burying himself in the interior of his family, and shrouding his existence, as it were, from every other eye; while the female sex, who, in Europe, form the ornament of society, are immured in the apartments of the haram, bought and sold almost as slaves. With all this is combined an outward deportment of great gravity, solemnity, and decorum, with which neither the sentiments nor actions are found to correspond. All this is more particularly true of the cities of Morocco; for in Algiers and Tunis, an unsettled government, and the habits of a seafaring life, have produced, especially in the lower orders, a greater appearance of activity and turbulence, though without any departure from the general tenor of oriental habits.

The *Letters* lately published, written by a female relation of Mr Tully, formerly consul at Tripoli, give a very lively picture of the manners of a Barbary court, and particularly of female society. This she had very peculiar access to observe, through the intimate footing on which she lived with the ladies of the palace. The wives of the bashaw, and the other grandees, are generally Georgian or Circassian captives, who are purchased at Constantinople at an early age, and trained in all those accomplishments which fit them for the harams of the great. By the Mahometan law, each individual may have four wives, and an equal number of concubines; but there is one principal wife, who alone shares the sovereign power. She has usually the same origin with the others, and enters the haram as a slave, but succeeds, by address and superior powers of captivation, in raising herself to this envied dignity. It is unlawful for the daughters of the sovereign to marry a subject; and as they do not usually form alliances with foreign states, they have no resource but to marry Turks and renegadoes, the refuse of the society. They thus often choose as companions for life, persons unworthy even to appear in their company. Accordingly, the husband is ruled with the most absolute sway, and treated usually worse than their slaves; to all which he quietly submits, in consideration of the lucrative offices to which this connection secures his advancement.

The toilet of a Moorish lady is said to be formed entirely after the ancient model. No dressing-table is used; but a number of slaves attend, to each of whom a different office is assigned. One plaits and perfumes the hair, another arranges the eyebrows, a third paints them, and so on. A profusion of the richest Arabian perfumes and scented waters is used, and powdered cloves, in vast quantity, are stuffed into the hair. The eyelashes are, by a very tedious process, painted black, and, by pulling out a number of the hairs, are formed into a particular shape. This operation, though attended with very

acute pain, is cheerfully submitted to. In short, a Moorish lady cannot be fully dressed under several hours; and her appearance is then so completely altered, that her nearest relations could scarcely be able to recognise her.

These ladies are represented, in the letters alluded to, as by no means spending their time, as usually supposed, in listless indolence. It is their task to overlook the numerous slaves who grind, spin, and perform all the necessary domestic offices. They are particularly expected to superintend the culinary operations, in order to guard against poison, the administering of which at meals is not unusual in these countries. These cares, with those of their family, fill up the time of the more amiable and domestic members of the haram; while those of a lighter turn find full occupation in the difficult and dangerous intrigues to which their disposition prompts them. With a few exceptions, however, they seem tolerably cheerful; and the view which these letters give of their character is, on the whole, favourable.

The inhabitants of the towns do not form a race by themselves, but are aggregated from the various races who inhabit, or have inhabited, the country districts—the Arabs, the Brebers, probably in part also the ancient possessors, and the Vandal conquerors of northern Africa. All these have been cast into that mould which Moslem despotism invariably forms. There is, however, a peculiar race, called Andalousie, descendants of those Moors, expelled from Spain by the stupid despotism of that government. They inhabit chiefly the northern cities of the empire of Morocco. They pique themselves on their descent, and seem to retain somewhat of that pride of birth which was probably formed during their residence in Europe.

The sciences, which anciently formed the glory of the Saracen name, are now, throughout the whole of this region, entirely extinct. Instruments are still shown, which display the most exquisite mechanical skill; but they are preserved merely as antique curiosities, without any knowledge of the principles by which they were constructed. Astronomy does not extend to the construction of a sun-dial, nor chemistry beyond the making of rose-water. With regard to medicine, the estimation in which that science, once so flourishing, is held, may be judged by the emolument reaped by its professors. The fee of a physician scarcely ever exceeds sixpence; and the most serious operations are performed for a shilling. These humble practitioners succeed tolerably, when only external wounds are to be healed; but in all internal maladies, it appears very doubtful whether most patients die of the disease, or of the remedies administered.

The Jews form a numerous class throughout all the cities, both of Eastern and Western Barbary. They seem to exist there nearly on the same footing as in Europe during the middle ages, the objects of universal hatred, contempt, and derision, and their plunder the invariable resource, whenever the sovereign finds himself in pecuniary embarrassment. Yet their knowledge of trade, and entire devotion to it, have almost secured to them the monopoly of mercantile and money transactions; and they are thus enabled to make such enormous profits as induces them to endure all this oppression. In Morocco, however, long suffering appears at length to have wearied their patience, and their numbers have been considerably thinned. In the capital, they are not now supposed to exceed 2000. No such diminution seems to have occurred in the other states. Tunis is calculated to contain above 15,000.

The country Moors, or those who cultivate the plains of Barbary, appear to differ very widely from the inhabitants of the cities. The property, or rather the occupation of land, is, as usual in despotic countries, much subdivided. The manners of the cultivators have been little observed, but they are said to be characterized by a peculiar degree of ignorance and simplicity.

The inhabitants of the pastoral districts intermediate between the sea coast and the Sahara, are known by the name of Arabs. They appear, in fact, to comprise such of the descendants of the conquerors of Barbary as have adhered to their original and native employments. They exhibit the same migratory habits, the same simplicity of life, and the same union of hospitality and plunder, which distinguish their countrymen in Arabia. The touch of despotism has, however, taken from them much of that sense of honour and dignity which elevate the latter above the common level of barbarous tribes. They live in tents, thirty or forty of which united form a camp or *douar*, under the command of a shiek: the supremacy over a number of these camps constitutes a Great Shiek or Emir. The tents are made by themselves, of camels' hair and the fibres of the palm tree; they are arranged generally in three concentric circles, around the habitation of the shiek. The cattle go out to pasture during the day, and are tended by the men and boys; at night they are withdrawn within the circle of the tents. They are farther guarded by a number of vigilant dogs, who bark incessantly. The complexion of the Arabs is of a deep copper. The females possess beauty when young, but quickly lose it. They adorn themselves by puncturing and tattowing, practices unknown to the other inhabitants of Barbary. When the spot occupied by a *douar* is exhausted, they remove to another; the women are then conveyed in groups generally of three, upon the back of each camel; while the children, lambs, and kids, are lodged in panniers on each side. The shieks embrace every opportunity of acting independently; and whenever a weak government or civil war occurs, immediately begin to plunder. Of all the inhabitants of Barbary, the Arabs are animated with the most bigoted zeal for the Moslem tenets, and the deadliest enmity to the Christian name. This disposition, the effects of which have been felt by all European visitors, has probably darkened somewhat beyond reality the picture drawn by them of these tribes.

From the inhabitants of the plains, we ascend to those of the mountain districts. The greater part of the declivity of the Atlas chain is cultivated by a very remarkable people, called the Brebers. They have been named also Brebes, Berebbers, Barbars; and from them the name of Barbary is supposed to be derived. The Brebers appear to be descended from the original possessors of this region; they view

Barbary States.

themselves still as its rightful owners, and regard with boundless indignation all the other nations by whom it is now occupied. Their subjection has always been very imperfect, and the slightest injury has been sufficient to drive them into rebellion. Their chiefs are elective, and they alone, in this part of Africa, have a government moulded into somewhat of a republican form. Their character is extremely warlike, and they excel the inhabitants of the plains in the management of fire-arms. The army of Morocco has often been completely defeated by them, and pursued to the gates of the capital. In general, however, they carry on war chiefly by surprise and ambuscade. The idea formed of them by the Saracen conquerors may be conceived by a passage in a celebrated Arabian writer (Bakoui), who gravely informs us, that they are the offspring of the giant Goliah, whom they resemble in strength and wickedness. They are divided into various tribes, of whom the Errifi, inhabiting a province of the same name between Algiers and Morocco, are the most powerful and ferocious.

The Brebers are distinguished from the other inhabitants of Barbary by a language which has nothing in common with any of the rest. It is considered by Adelung to be the same (allowing for some variation of dialect) with that of the Tibbo, the Tuarick, and of all the indigenous population of this part of Africa. Marsden and Langles have supposed it to be a corruption of the ancient Punic language; but Mr Pinkerton forcibly argues, that a language which has no abstract terms, none belonging to the arts and sciences, and no written characters, could scarcely be even a corruption of the language of a civilized people. Its high antiquity, however, cannot be doubted.

The Shelluhs inhabit the southern parts of Morocco. They are smaller in stature than the Brebers, and in character somewhat less rude. In all other respects, they exactly resemble, and may be considered as a branch of that race. Some writers have asserted their language to be different; but the vocabulary given by Chenier, and the information of Dupuis, seem to leave no doubt that it is merely a dialect with very slight variations.

To these different classes we may finally add one which is not inconsiderable,—that of the negroes. Originally brought as slaves from Soudan and Tombuctoo, they have multiplied greatly, and have even risen to distinguished estimation. The sovereigns of Morocco, unable, from the natural jealousy of despotism, to trust their own subjects, have placed their entire confidence in negro troops. These form the standing army of the empire, the body guard of the sovereign, and the garrison of all the principal fortresses. Their pay is very small, not exceeding a penny a-day; but its smallness is compensated by the licence in which they are allowed to indulge. A person, well acquainted with Morocco, being asked what their pay was, answered, "Whatever they can rob or steal." Muley Ishmael maintained nearly 100,000 of these troops. Their fidelity to their monarch is said to be exemplary. Negro slaves still continue to be imported in great numbers, particularly into Morocco.

Political State of Barbary.

We proceed now to take a view of the political state of this extensive region, which has sustained no change from the lapse of time, and is that of a savage, uncontrolled, and turbulent despotism. In Turkey and the Asiatic empires, there are public bodies, rendered venerable by religion, by law, and even by knowledge, who share and moderate the power of the despot. In Barbary, there are none such; the will, or rather momentary caprice of the sovereign rules every thing. Yet the throne, though thus absolute, is not thereby rendered secure; resting on no basis, it is overturned by the slightest storm that arises. The death of a sovereign is almost invariably followed by disputed succession and civil war; so that tranquillity, the sole boast of despotism, is not even secured by it to this unfortunate country.

Morocco.

The present sovereign of Morocco is named Muley Soliman. He has three brothers, two of whom contended with him for the sovereignty, and being overcome, now live in exile. He is about forty, rather handsome, and of a quick comprehension. He is a *fakih* or doctor, deeply versed in the Mahometan faith, and passes the greater part of the day in prayer. His religious austerity prompts him to shun every appearance of luxury in his dress and manner of life. Requiring still greater simplicity in his ministers and attendants, he has completely banished that splendour which usually accompanies a court. The most pernicious effect of this bigotry consists in the hostility with which it inspires him against various branches of industry. He has ordered all the plantations of tobacco to be destroyed, because, although the prophet has not forbidden the use of that plant, there is no evidence of his having used it himself. In the same spirit, he opposes every possible obstruction to commerce with Europeans, whom, as infidels, he regards with horror. In other respects, his government is said to be milder than that usually experienced by the people of Morocco.

Algiers.

Algiers holds the next rank; but nearly a century has elapsed since any narrative of its internal state has been published by any European visitor. The most recent information regarding its interior that we have seen, is contained in an American publication, drawn up from the statements of the American captives who were confined there from 1793 to 1795. At that time the Dey was a Turkish soldier, named Hassan, about fifty, who had been brought from near Smyrna in the year 1786. Having insinuated himself into the favour of the reigning monarch, he gradually rose through the different offices to that of prime minister. The old Dey dying, Cedelli, a Greek, and a creature of Hassan, urged, and even ostensibly compelled him to assume the sovereignty. He prevailed; and another candidate who started up was put to death by the bowstring. There have probably been several changes since; and a new Dey is said to have come into power within the last six months. The Divan, it appears, have lost almost entirely the influence which they once possessed, and do little more than sanction the measures determined on by the Dey.

The present sovereign of Tunis is called Hamooda Bey, and is certainly an extraordinary character. He

Tunis.

has displayed a most energetic policy, and has seated himself more firmly on the throne than any of his predecessors. He is now (1816) about fifty-five years of age, and has reigned twenty-nine, a period quite unexampled in the tumultuous annals of Tunis. He has, in a great measure, thrown off that dependence on the Turkish power, by which the state was formerly enthralled; he even chooses his ministers and favourites, in preference, out of other nations. The mere vigour of his character and administration seems to have freed him from that dread of conspiracy and insurrection, by which former Beys were perpetually haunted. His brother, and his two cousins, though the rightful heirs to the throne, live on the most friendly terms with him, and partake of all his amusements. He extends a very liberal protection to all classes of his subjects, even Christians and Jews, who, before his time, might be insulted or killed with perfect impunity. He is indefatigable in the dispatch of business, and spends very little time in sleep, or in the haram. At seven in the morning, he generally receives the consuls of foreign nations in the hall of audience. From eight to twelve, he sits in the hall of justice. He is supreme judge throughout his own dominions; all his subjects, from the highest to the lowest, attend and plead their own cause. Unfortunately, wherever the Bey's personal interest is concerned, justice is entirely out of the question. His hand is always open for bribes from either party, and sometimes from both. Where such all-powerful motives do not interfere, he administers justice with equity, and even discovers a peculiar tact in eliciting the truth. His decisions are always given and executed with equal promptitude. Upon the whole, the security of person and property, and the general state of society, has been greatly ameliorated since his accession to power. Nothing seems to prevent him from being a good prince, except an avarice which knows no bounds, and hesitates at no means of gratification. This induces him to restrain the freedom of trade, to load it with monopolies, and often, which is worst of all, to become a merchant himself. He takes every opportunity of extorting money from his opulent subjects, without any pretence, and by the most arbitrary exactions. The following affords a curious example of Tunisian economy. He has erected a new palace, which will, it is said, be one of the most splendid edifices in Barbary; but, in order to lighten the expence, the ground floor has been fitted up into shops. He has given up the use of wine, in which he formerly indulged to great excess; but he is much addicted to other shameful species of debauchery.

The ministers and favourites of Hamooda are of the lowest description, both as to birth and character. The Zapatapa, or keeper of the seals, and Soliman Kiaya, commander of the army, are both Georgian slaves. The former is stained with every vice, but the latter exhibits an honourable and humane disposition, very rare in this country. The Bey's private secretary is a Christian slave; and the important and lucrative post of guardian of the slaves is held by a Neapolitan renegado.

For some time past, a furious war has raged between the states of Algiers and Tunis; the former, the more powerful of the two, being ambitious of conquering its weaker neighbour. The Bey of Tunis can call out a force of from 40,000 to 50,000 men; but they are merely an armed mob, and scarcely present the semblance of a regular army. The Algerine troops, however, are precisely of the same description. In the spring of 1807, the two armies took the field. That of Tunis was highly appointed, and thought of nothing less than the conquest of the Algerine province of Constantina. But so soon as the advanced guard of the Algerines was seen reconnoitring, the whole Tunisian army turned, threw down their arms, and fled with the utmost rapidity in every direction. Many are said to have arrived at Tunis, without having once ventured to look behind. The Algerines took possession of their camp, baggage, and 15,000 camels, laden with every kind of supplies. It is supposed that nothing but the dread that so easy a victory might be the effect of stratagem, prevented the enemy from marching forward, and entering Tunis.

The army of the Bey, however, reassembled almost as quickly as it had dispersed; and in July he was again able to take the field. On the 13th, the two armies approached each other; and the advanced guards having met, the troops of Tunis began to fly in confusion. But a Greek slave having ventured to fire a cannon, the Algerines took the alarm, and retreated precipitately to their own camp. The Tunisians having thereafter rallied, the two armies remained all next day in sight of each other. In the evening, however, Soliman Kiaya, having gone up the mountains to reconnoitre with a small body of cavalry, the Algerines began to dread, that an attempt was making to surround them; upon which, the whole army broke up, and fled precipitately in every direction, leaving their camp, baggage, and 10,000 camels, in the hands of the victors. The latter, satiated with plunder, were not inclined to advance, otherwise they might easily have taken possession of Constantina. We need scarcely add, that such combats were not attended with serious bloodshed; they were sufficient, however, to deter these heroes from again taking the field, and the war was thenceforth carried on by petty skirmishes.

Tripoli.

The government of Tripoli presents a still darker picture than that of Tunis. The flourishing era in the history of this state, was the reign of Hamet the Great, at the commencement of the last century. He freed Tripoli from the Turkish yoke, in a manner worthy indeed of so barbarous an administration. He invited to a feast 300 of their chiefs, each of whom, as they successively entered, were strangled. At the same time, a general massacre took place in the city. The Porte being propitiated by presents, he was left to reign in tranquillity. He reduced to complete subjection the hitherto untractable possessors of the mountain districts of Garian and Mesulata; and even succeeded in rendering Fezzan his tributary. He invited foreigners to settle in his dominions, and promoted the manufactures of woollen stuffs, Morocco leather, &c. His popularity enabled him to render the crown hereditary in his family. The late Bashaw reigned for thirty years with great moderation and mildness; and Tripoli assumed a civilized and pacific character, very unusual in this part of the world. A

Barbary States.

most unfavourable change has taken place in his son Yusuf, the present Bashaw. He began his career by murdering his elder brother, an amiable prince, in the most barbarous manner. Then surrounding himself by negro slaves and Arabs, he gained an ascendancy over the more pacific inhabitants of the city. He thus succeeded in driving out his second brother, and seizing on the sovereignty. He is represented as uniting in himself all the vices of that worst of characters, a Barbary despot. He has, in a great measure, ruined commerce, by monopolizing to himself all the lucrative and important branches. His principal minister is Sidi Hamet, who shares with his master the most decided partiality to the French, and enmity to the English. Lord Nelson, in 1798, sent a line of battle ship to demand that the Bashaw should for ever remove from his councils so dangerous a subject. A feigned compliance took place, but lasted only till the English ship was out of sight of Tripoli. This personage has since been raised to a higher situation, that of minister for foreign affairs, while his creature Mustapha has been appointed captain of the port. The place of first admiral is held by a person bearing the name of Murat Rais, but who is in reality a Scotsman, named Peter Lysle. Being at Tripoli in 1792, as mate of an English vessel, and accused of plundering part of the cargo, he fled to the castle, embraced Mahometanism, and received a command in the Tripoline navy. He soon distinguished himself in the capacity of a pirate, and rose by degrees to his present high situation. He is said, however, to enjoy it but little, and to sigh still for the loss of his country, and his friends.

Religion.

The religion of Barbary is well known to be throughout Mahometan, professed with a degree of rigour and intolerance unknown in any other region of the globe. There is not, however, as in Turkey, any great body, like the Ulema, to act as the depositary of its doctrines and influence. This influence is here enjoyed by individuals who raise themselves, by personal merit or demerit, to the character of saints. Saints, in Morocco, almost share with the sovereign the power of the empire. Sidi Ali and Sidi Alarbi are the two most eminent reigning saints. Their consideration is chiefly supported by working miracles, and does not require any sacrifice of the pleasures of life. They indulge in all these without reserve, and, besides the usual number of wives, keep numerous concubines. The districts in which these saints reside pay no taxes, and are subject to no authority, except theirs; and they are perpetually surrounded by a body of armed men, to chastise their own enemies and those of the prophet. At some distance from Tripoli, there is a fortified village possessed by a saint, called the Lion, which serves as an asylum for every species of criminals, even those who are guilty of high treason. Idiots, throughout Barbary, are generally reputed saints; and some, in order to maintain the reputation of sanctity, find it expedient to counterfeit the total absence of reason.

[Am]ount of Population.

The population of Barbary has been very variously reported, and has never been fixed on any precise or authentic *data*. We shall collect the different statements made on the subject. Mr Jackson gives the population of Morocco at 14,886,600; of whom the cities and towns contain 895,600; the provinces within Atlas 10,341,000; the Berebbers amount to 3,000,000, the Tafilets to 650,000. He states these numbers to be founded upon information extracted from the Imperial Register. They are quite improbable, and very far beyond any estimate formed by preceding travellers. Chenier does not conceive that the empire can contain above six millions; and some have even reduced the estimate so low as two. Mr Macgill heard the population of the Tunisian territory generally estimated at five millions; but is inclined to reduce the estimate to half that amount. Of these he supposes that 7000 may be Turks, 100,000 Jews, 7000 Christians; the rest Moors, Arabs, and renegadoes. Of the Algerine territory we have seen no estimate; but being more extensive and equally cultivated with that of Tunis, it must contain a greater population. Tripoli is reckoned by Ali Bey to contain two millions; probably beyond the truth. Of the great cities, Morocco is generally supposed to contain 30,000; Fez, by Jackson, 380,000; by Ali Bey, only 100,000; Tunis, by Mr Macgill, 100,000; by Mr Blaquiere, 130,000; Algiers, by Dr Shaw, 117,000; Tripoli, by Mr Blaquiere, 25,000; by Ali Bey, only 15,000.

Commerce.

With a soil so fertile, and where manufacturing industry is in so low a state, the productions of the earth must form the staple articles of export. Barbary, in ancient and even in modern times, has been the granary of southern Europe. Of late, however, this branch of trade has been nearly cut off by a general prohibition, in all the states, against the exportation of corn. The materials for export are thus reduced to fruits, gums, hides, wax, and the produce of the very few manufactures which flourish throughout these states. Of these, Morocco leather is the most important. Fez is the place where this manufacture flourishes in the highest perfection; but it is also carried on in the other cities of Morocco, as well as those of Eastern Barbary. Fez is also distinguished by the manufacture of woollen haiks, a species of long cloths universally worn by the Moors when they go abroad; of sashes and silk handkerchiefs; and of carpets, which are little inferior to those of Turkey. Tunis is famous for the manufacture of a species of conical woollen caps, called scull-caps, universally worn, not only in Barbary, but over the Levant. This fabric formerly employed fifty thousand persons; but the manufacturers of Leghorn and Marseilles now imitate it, and succeed in underselling the Tunisians, though, in the quality of the stuff, the latter remain still unrivalled. Robes and shawls of woollen gauze are also made to a great extent. Concerning the manufactures of Algiers and Tripoli, we have few details; but with the exception of caps, they appear to be nearly similar to those of Tunis.

The caravan trade with the interior of Africa is chiefly carried on from Morocco and Tripoli. From the former it is very extensive. The caravans carry chiefly salt, tobacco, and European goods; they bring back slaves, ivory, and gold dust. Lempriere estimates the amount of the former at one million; the latter at ten millions; which, if correct, would imply the profits on this trade to be immense. The

Barbary States.

trade from Tripoli has been greatly diminished, in consequence of the Bashaw having embroiled himself with his Arab neighbours, who, occupying the route by which the caravans must pass, render the communication extremely precarious.

The European goods for which there exists a demand in the Barbary States, are exceedingly various. They include more or less of almost every article both of manufacture and of colonial produce. In the former class are such articles as, being of inferior quality, can be afforded at a cheap rate; Yorkshire cloths, particularly druggets and serges; muslins of the coarsest and cheapest sort; coarse linen, particularly German. Raw silk and Spanish wool were imported to a great extent when their manufactures were more flourishing. French wines are imported into the eastern states, where the precepts of Mahomet are less rigidly observed. The other imports are tin and lead to a considerable extent, English is preferred; coffee, sugar, and the different kinds of spices: hardware, cutlery, toys, are in some demand; also alum, vitriol, cochineal, gum-lac, and vermilion, for their manufactures.

The commerce of Morocco is greatly diminished by the senseless bigotry of the reigning Emperor. The intercourse with Europe is now confined to the port of Mogadore, and is subject to various restrictions. The articles of export, suited to the European market, appear, by Mr Jackson's enumeration, to be chiefly sweet and bitter almonds, about 1,000.000 lbs.; gum Barbary, gum Senegal, and gum Sandarac, upwards of 100,000 lbs.; cow and calf skins, 260,000 lbs.; goat-skins, 10,000 dozen; wool, 30,000 lbs.; ostrich feathers, olive oil, citrons, and some minor articles.

The commerce of Eastern Barbary has hitherto been carried on chiefly from Leghorn and Marseilles. Louis XIV. established at the latter port a Royal African Company, which formed several establishments upon the coast of the Algerine province of Constantina. The objects were the corn trade and the coral fishery, which they shared at first with an English company already established; but the latter failing, the whole trade fell into the hands of the French. Their first establishment was at the *Bastion de France*, at the western extremity of Algiers; but this was abandoned, and they settled at La Cala, Bona, Il Col, and Tabarca. They paid L. 4000 a-year to the Dey of Algiers, and 100 *per cent.* to the Bey of Constantina, on the grain exported; in addition to which, they were obliged to submit to various species of extortion and humiliation. The Continental war, and the extinction of the French naval power, threw a large proportion of this trade into the hands of the British; and Malta became the channel through which it was conducted. In 1806, the British Government contracted with the Dey of Algiers for the possession of La Cala, Bona, and Il Col; in consideration of which, they stipulated to pay him the sum of 50,000 dollars (L. 11,000 Sterling). Mr Blaquiere, and other persons acquainted with this coast, are of opinion, that very important advantages might be derived from this settlement. The coral fishery alone might employ 500 boats and 9000 men; besides which, there is a large export of hides, wax, and wool. It is added, that the country produces ship-timber, particularly oak, of the best quality, and in inexhaustible abundance, and that excellent hemp and flax might be raised. As yet, however, the British Government have continued to pay the money, without forming any establishment, or deriving any benefit from the privilege thus purchased. The coral fishery is carried on by a small number of French and Neapolitan boats; and the spirited attempts made by the merchants at Malta to open a communication with this quarter have been frustrated. From the pressure of the war, or other causes, no military establishment has yet been formed at La Cala. The place, however, is said to be admirably suited for such a purpose, and, at a very small expence, might be rendered impregnable.

Christian Slavery.

We shall finally consider these states under the view, which has so justly excited the interest and sympathy of the British nation, that of Christian slavery. To be placed under the absolute control of the most brutal and corrupted of mortals, whom religious antipathy has divested besides of every human sympathy—without any law or earthly power to appeal to—the hopeless victims of brutal cruelty, and still more brutal voluptuousness;—this is certainly the most dreadful fate to which human beings were ever devoted. Yet such has been the fate of thousands of Europeans, among whom were often those who, from rank, sex, and cultivation of mind, must have been most keenly sensible of its horrors. Painful as the subject is, it seems indispensable to give some details which may illustrate the extent of the evil, and the necessity which existed for some arrangements to remedy it.

The most particular and authentic account of the treatment of slaves at Algiers is that given in the American work already alluded to. On the 23d October 1792, the ship President saw approaching an armed xebeck, bearing Spanish colours, till she came within gun-shot, when she instantly hoisted the bloody flag, and fired. Escape was now impossible; the xebeck instantly put out a boat, with thirty armed men, who rowed furiously towards the vessel, and boarded it with the wildest shouts and outcries. No resistance being made, they began to strip the crew with a fury of avarice, of which it was impossible to form an idea. Sometimes several fell upon one American, and fought over him for the clothes of which he was stript. Having ransacked every corner, they then ordered the Americans to descend into the boat; and those who showed any hesitation were instantly knocked down, and kicked over into it. On reaching Algiers, the distribution took place. The Dey made first his choice, which was formerly limited to an eighth of the whole, but now extends to as great a number as he chooses to demand. For this purpose, they were conducted to the palace, and drawn up in files along a court, where they passed under this review. Having made his selection, he dismissed the rest with the compliment, "Go, you Christian dogs, and eat stones." The youngest were employed in menial offices about the palace, the rest were put to work in the marine and in public buildings. Whenever a foreign vessel was in the port, they were loaded with thirty or forty pounds weight

of chains, in order to prevent their escape. Their heaviest labour consisted in dragging immense stones from a neighbouring quarry, for the repair and enlargement of the mole. A body of Turks attended to urge them on, but gave no aid, unless by continually roaring out *Hyomoly*, "heave away," with a noise so tremendous, that it was heard at the distance of more than a league. At night, they were locked up in two huge buildings, called bagnios, the lower part of which was employed for shops, and the upper for the joint accommodation of the captives and of the wild beasts belonging to the Dey. There was no bed in the place, and they were obliged to lie on the floor, till their own ingenuity enabled them to erect some humble substitute. The daily allowance of food was a pound of very bad bread, and a small quantity of oil. Many sunk under this accumulation of distress, and were carried to the Spanish hospital, the only relief provided for their miseries. The sympathy of the American people having been at length excited by reports of their sufferings, they opened a negociation, and, at the expence of nearly 800,000 dollars, procured the release of the captives.

The observations made by Captain Croker, during his visit in 1815, agree with the narrative of the Americans, and prove that no improvement had taken place since that time. At the period of his arrival, three hundred Christian captives had been driven in from Bona, exposed to such treatment that fifty died within six days after reaching Algiers. They were still employed in the quarries, and loaded with chains, as before. His description of the house in which they were locked up is, that, "if it had light," it would resemble those in which the West Indian negroes keep their pigs. Being now at peace with the great powers, their piracy is chiefly exercised on Naples and Sardinia, with whom they have always taken care to continue at war. European, and even English colours, are assumed to entrap the unfortunate victims. They frequently also make descents on the coast, and sweep away all the inhabitants, without distinction of age and sex. The Tunisians, at the commencement of the reign of the present Bey, landed on the island of St Pierre, belonging to Sardinia, and carried off the whole population, amounting to upwards of a thousand. At Tunis and Tripoli, the treatment of slaves is not so utterly inhuman as at Algiers. The most dreadful fate is that of those who are judged fit to be received into the haram of the prince, or any of his principal officers; which, in consequence of the depraved propensities here prevalent, is not confined to one sex. Of those who become the slaves of private persons, both at Tunis and Algiers, some are tolerably, and a few very well treated.

It is not easy to ascertain the precise extent in which this enormous evil lately existed. Mr Blaquiere, though he represents its horrors in the most glowing colours, considers the whole number of captives as amounting only to a thousand. Mr Macgill calculates two thousand in Tunis alone, and the Americans the same number at Algiers. The first estimate, however, is probably the more correct, as, by a calculation of the amount and rate of ransoms returned, the number in Algiers, at the time of Lord Exmouth's first expedition, appears to have been four hundred and fifteen.

The outrageous conduct of the Barbary corsairs has repeatedly roused the indignation of the principal European states. Yet it has happened, that most of the expeditions undertaken to repress or intimidate them have been not only unsuccessful, but attended with the most disastrous issue. We may particularly mention the expedition of Charles V., which will be found narrated in the body of the work. More recently, in 1776, the Spaniards sent a large fleet into the road of Algiers, which landed 13,000 or 14,000 troops. Through a want of harmony, however, between the commanders, the army reimbarked, and the fleet sailed off without attempting anything of importance. They returned in 1783, when the fortifications were greatly strengthened, but by means of gunboats, they were enabled to bombard the city in a terrible manner. Yet the Dey, though obliged to leave his palace, was neither moved by his own danger, nor by the sufferings of his subjects, to sue for peace; and the Spaniards at length retired. They returned next year; but the Dey had now prepared a large force of gunboats, which kept them at a distance; and they were obliged to move off, without having effected anything whatever. The Algerines now believed themselves invincible; and the Spaniards were fain to purchase peace with a million of dollars, besides a large sum for the ransom of their captives.

In 1800, the Americans waged war against Tripoli, in consequence of a vessel belonging to them having been seized, and the crew made slaves. They repeatedly attacked the harbour, and did some damage to it, but were not able to make any serious impression, or to produce any effect, besides that of impelling the tyrant to a more rigorous treatment of his captives. They then adopted a different course. They landed in Egypt, where they were joined by Hamet, the elder brother of Yusuf, the reigning Bashaw, and to whom the throne rightfully belonged. The confederates having collected 500 men, marched through the Lybian desert, and took Derne, the frontier town of Tripoli. Notwithstanding the smallness of this force, Yusuf, alarmed by the popularity of his brother, accepted the mediation of the Danish consul, and a treaty was concluded. The prisoners were restored at a moderate ransom, and Hamet, now abandoned, returned to Egypt. Upon the whole, there seems to have been very little ground for the boast which has been made, respecting the conduct and success of this American expedition.

After the termination of the Continental war, which had absorbed every other interest, a deep feeling was excited in the British nation, for the fate of their fellow Christians, who were groaning under this horrible slavery. Sicily and Sardinia, the chief sufferers, were our intimate allies; besides which, Britain, as mistress of the seas, seemed called upon to put down a system of naval warfare and depredation, inconsistent with all those ties by which civilized nations are united together. Urged by this impulse, the British Government directed Lord Exmouth (late Sir E. Pellew) to sail with a squadron against Algiers and

Tunis. The appearance of this armament was sufficient to induce both states to a compliance with the terms demanded, which were, peace with Sicily and Sardinia; the restoration of their captives at a moderate ransom; and an engagement, in every future war, to treat prisoners in the manner customary among civilized nations. Scarcely, however, had this treaty been signed, when it was violated, on the part of Algiers, in the most outrageous manner. Several hundred boats, chiefly Neapolitan, being employed under sanction of the British flag, in carrying on the pearl-fishery on the coast near Bona, a gun was suddenly fired from the castle, when two thousand Turks and Moors rushed down upon the unfortunate fishermen, and, aided by fire from the forts, massacred the whole of them. The English flag was seized, and trampled under foot. Lord Exmouth had already sailed, and was arrived in England before he heard of this dreadful tragedy. The utmost expedition was then employed to equip a new and more formidable armament. In a few weeks Lord Exmouth again sailed, and being joined at Gibraltar by a Dutch squadron under Admiral Capellen, arrived before Algiers, on the 26th August last (1816), about three months from the time at which he had left it. On the morning of the 27th, a flag of truce was sent in, stating the conditions on which alone peace would now be granted, and allowing two hours for their acceptance. Three hours elapsed, without an answer, but also without any hostile movement; and Lord Exmouth began to hope the intentions of the Dey might be pacific, when several shots were fired from the harbour. A combat of the most terrible description immediately began, the batteries being attacked with all the characteristic valour of British seamen, and defended with all the fury of barbarian desperation. The British fleet suffered severely; but after seven hours fighting, the enemy's batteries were reduced to a state of ruin; and the flotilla having succeeded in setting fire to some of the Algerine vessels, the flame spread to such a degree, that the whole fleet, arsenal, and gunboats, were ere long reduced to ashes. On the following morning, the Dey submitted unconditionally to the terms prescribed by the British Government. These were—the abolition, for ever, of Christian slavery; the immediate delivery, to Lord Exmouth, of all captives, of whatever nation, who were within the territory of Algiers; the repayment of the ransoms formerly received; with apology and reparation to the British consul, for insults that had been offered to him. All these stipulations were executed with the utmost promptitude.

Thus terminated an achievement, than which none has ever reflected a purer glory on the British name—one undertaken, not from any merely British motives, but to defend the general cause of humanity, and vindicate the rights of the civilized world. All observers agree that, in the case of a race at once mean and barbarous, fear is the only motive which can act with sufficient force; and that a signal chastisement, such as cannot be soon forgotten, affords the only security for their future moderation. The lesson which the Algerines have now received is of this description; and there is therefore every reason to hope that its influence may be long and salutary.

Brooklyn, 1800. (B.)

BARLOW (Joel), an American literary and political character of considerable note, was born in the year 1756, in the village of Reading, State of Connecticut; and appears to have been the youngest of ten children. His father died when he was yet a boy; but his friends, attentive to his instruction, employed his portion of the paternal inheritance for his education, at the college of Newhaven, in his native state. Here he commenced his studies in 1774. In the course of the prescribed exercises of composition, he discovered a taste for poetry; and two productions crept into public view; one entitled *The Prospect of Peace;* the other, *An Elegy on the Death of Mr Hosmer*, Member of the American Congress. It appears that Mr Barlow was destined for the clerical profession; and that his friends solicited and obtained for him the appointment of chaplain to a militia company of Massachusets, the functions of which he performed till the event of peace. One of his panegyrists has observed, in reference to his subsequent change of profession, that, "amongst the Presbyterians of New England, the priesthood is nothing else than a species of civil ordination. He who receives it may pass to another employment; and it is common enough to see young men preach the gospel in order to have time to prepare themselves for another profession." This explanation, however, is hardly reconcileable with the spirit of the New England theologians, who even now require from the candidate for holy orders a solemn declaration, that he is moved to this calling by a certain species of inspiration, or divine impulse, and not by any carnal or interested motive.

In 1781, while he followed the army in quality of chaplain, he contracted a marriage with Miss Baldwin of Newhaven; and it was during this period of his life that he planned the edifice of his future fame in his poem destined to celebrate the discovery and prospects of America.

It was also during this period that the patriarchs of Connecticut proposed to adopt a new metrical translation of the Psalms, which excited to emulation all the poetical genius of the state. The version of Barlow carried the prize; and is to this day sung in the churches of New England.

At the conclusion of peace between the United States and Great Britain, he abandoned the ecclesiastical life, and settled at the village of Hartford, where, two years afterwards, he published the poem alluded to, entitled, *The Vision of Colum-*

bus, which he afterwards gave to the world in a more expanded and imposing form.

After quitting the service of the church, he appears for some time to have practised law; but, in 1788, he likewise abandoned that profession to become the agent of a mercantile company, who had purchased some millions of acres of lands situate on, or near the river *Ohio*, which they proposed to sell to foreigners at an enhanced price. For this purpose, Mr Barlow was sent to Europe; and it is said that he was fortunate in the execution of this commission.

Having during this period become deeply interested by the events of the French Revolution, he published, in the years 1791 and 1792, the following political pieces: 1. *Advice to the Privileged Orders.*—2. *The Conspiracy of Kings.*—3. *Letter to the National Convention of France.*—4. *The Royal Recollections.* Towards the end of the year 1792, he was, being then in London, appointed by the Constitutional Society of London one of a deputation to present an address to the National Convention of France,—a circumstance which attracted the notice of the British Parliament, it having been stated by a member that the Convention had received an address by means of two *fellows* calling themselves the representatives of Great Britain, viz. Frost and Barlow.

In 1793, Barlow, from motives of curiosity, accompanied the four commissioners of the National Convention who were sent to Montblanc, to organize that department; and this excursion gave rise to another production, entitled, *A Letter to the People of Piedmont.* He also translated about this time Volney's well known work, entitled, *Ruins of Empires.*

Objects of a commercial nature at length drew him to Hamburgh, and afterwards to the coast of Africa, where he received the commission of consul-general of the United States, with instructions to enter into and conclude treaties with the Barbary powers, for the purpose of procuring the ransom of the American citizens who were detained as slaves in those countries. The execution of this commission was prompt and fortunate; and, after residing for some time in Paris, to which he returned from Barbary, he, in 1805, proceeded to America, and purchased a neat habitation in the territory of Columbia, the seat of the general government, to which he gave the name of *Kahrama.* Here he formed an acquaintance with certain considerable members of Congress, to whom he greatly recommended himself by the publication of a short sketch of a plan of national education, and an address to the citizens of Washington upon occasion of one of the anniversaries of American independence. He now also published the superb quarto edition of his national poem, to which he finally gave the name of *The Columbiad.*

Soon after his return from Europe, he was admitted to the confidence of the first magistrate of the United States; and, in 1811, he received the valued appointment of minister-plenipotentiary to the court of France. This nomination met with powerful opposition in the Senate, and passed only by a small majority.

He sailed for his destination on board of the Constitution frigate, disembarked at Cherburg in September 1812, and proceeded to the French capital, where he was received, in the Emperor's absence, by the minister of foreign affairs, who "was instructed to say the most flattering things relative to his appointment." The great object of his mission was to obtain compensation for the American property confiscated in virtue of the Berlin and Milan decrees. This arrangement was to be regulated in a manner the least onerous to the French treasury. American ships and cargoes were, at the same time, to be freed from unjust detention, and a new commercial treaty to be formed on principles of national justice and reciprocity.

In pursuit of this object, he followed the Emperor Napoleon to Wilna, in the memorable winter of 1812; but this diplomatic journey was without advantage, and the failure was the more mortifying, as it was undertaken without the advice or instructions of the American Government. Mr Barlow was returning to Paris, when he was seized with a violent inflammatory disease, of which he died, on the 26th of December, in the 58th year of his age. His nephew, late midshipman on board of the Constitution frigate, whom he took from his studies to accompany him in this journey, and a secretary of the French Legation in the United States, were witnesses of his last moments, and saw him interred at the place where he closed his eyes, an obscure village of Poland.

Of the private life of Mr Barlow there is but little to say. He was of a very taciturn disposition; and though he had lived so long abroad, was in manners and appearance a true New England man. His life was sober and uniform. His court dress, though plain, he called his *harness.* He left no issue; but his wife survived him, and returned to America, to the enjoyment of considerable property bequeathed by her husband.

To this account of Mr Barlow, for which we are indebted to a correspondent abroad, to whom he was known, we shall subjoin the estimate which has been formed of his great work the *Columbiad,* by a very competent critic. "In this poem, the whole history, past, present, and future, of America, is delivered in the clumsy and revolting form of a miraculous vision; and thus truth is not only blended with falsehood and fancy, but is presented to the mind under the mask of the grossest and most palpable fiction.—From the prose which he has introduced into the volume, and even from much of what is given as poetry, it is easy to see that he was a man of a plain, strong, and resolute understanding; but without any play or vivacity of fancy, any gift of simplicity or pathos, any loftiness of genius, or delicacy of taste. Though not deficient in literature, nor unread in poetry, he had evidently none of the higher elements of a poet in his composition; and has accordingly made a most injudicious choice and unfortunate application of the models which lay before him. Instead of aspiring to emulate the sub-

Barlow || Barometer.

lime composure of Milton, or the natural eloquence and flowing nervousness of Dryden, he has bethought him of transferring to epic poetry the light, sparkling, and tawdry diction of Darwin; and of narrating great events, and delivering lofty precepts, in an unhappy imitation of that picturesque, puerile, and pedantic style, which alternately charms and disgusts us in the pages of our poetical physiologist." (*Edinburgh Review*, Vol. XV.)

BAROMETER.

The *Encyclopædia* contains such an account of the discovery and construction of this most valuable instrument, as could be drawn from the popular treatises of natural philosophy in the English language. But, unfortunately, our compilers of elementary works have seldom taken the trouble to remount to the original sources of information, and have frequently, by substituting their own fancies, or servilely copying the mistakes of others, contrived to disfigure egregiously the relation of facts, and the history of the progress of invention. We now purpose, therefore, as far as our limits will admit, to remodel the article; and, passing rather slightly over the description of the different kinds of barometers, and other practical details already given, to dwell more especially on the successive steps which led to the fine discovery of atmospheric pressure, and its application to physical science.

Opinions of the Ancients:

The opinions entertained by the ancients concerning physical subjects, appear at best only splendid visions. They speculated boldly in cosmological theories, but were easily satisfied with those conclusions which merely soothe the fancy. Many of the philosophical notions, however, adopted in remote ages, have left a durable impression in the structure of language, and still continue to exert a visible influence in moulding the current sentiments of mankind. The early sages of Greece distinguished matter into the four primary elements, of earth, water, air, and fire, which, by their various combinations, were supposed to produce the animated spectacle of the universe. With these elements were associated corresponding qualities, in a binary conjunction: Hot and cold; dry and moist. Earth and water were considered as ponderous and inert; but air and fire, endued with elastic virtue, were imagined to possess lightness and activity. Fire, though extracted from all bodies by the operations of nature or of art, was yet conceived to be derived, by invisible emanation, from that diffuse lambent fluid, which, under the name of Æther, occupied the highest heavens, and constituted the substance and nutriment of the celestial bodies. While the earthy matter would, therefore, naturally settle towards the centre, and the aqueous fluids roll along the surface, of the solid globe; the air and fire soared aloft, the former occupying the whole of the region below the moon, and the latter streaming through the boundless extent of space. This sublunary scene is exposed to incessant change, calamity, and decay; but above it was supposed to reign a perpetual calm, the seat of bliss, and of divine and imperishable essence.

Aristotle, and some other philosophers, viewing æther as altogether distinct from culinary fire, were disposed, however, to consider it as a *fifth* element, of a pure, divine, and incorruptible nature; an opinion which afterwards gave occasion to the famous *Quinta Essentia*, or *Quintessence* of the schoolmen. The alchemists, who sprung up nearly about the same benighted period, in adopting those notions, modified them to suit their own peculiar views. To the elements commonly received, they joined the active auxiliaries of *mercury* and *sulphur*. For *quintessence* they substituted *spirit* and *elixir*; the former, drawn off by the application of fire, being conceived to represent the animating principle of each body; while the latter, extracted by the combined action of heat and moisture, was supposed to exhibit its concentrated and most select qualities.

and of the Schoolmen.

Some of the ancient cosmologists supposed a vacuum beyond the shining expanse of æther, destined to receive the exhalations from this nether world. Others denied the existence of a separate void, but admitted small vacuities interspersed through bodies. Aristotle, however, maintained the necessity of a plenum, asserting that our idea of space or extension is inseparable from that of body. To this principle he ascribed the suspension of water in a tube, when the finger is applied to shut the upper end. Yet the very contempt in which that philosopher, from a consciousness of his own superiority, was accustomed to hold the received opinions, might have led him to take juster views. He rejected the notion, that air has levity inherent in its nature; nor would he admit the more plausible idea, that a fluid so easily moved must possess the quality of perfect indifference, and be neither light nor heavy. Aristotle not only maintained that air is ponderous, but did not scruple to appeal to direct experiment in support of his assertion. A bladder, he says, will be found to gain some weight, on being blown or filled with air. But this was evidently a mere random assertion, betraying his ignorance of the constitution of fluids. A bag filled with air, and suspended in a like medium, it is obvious, from the laws of hydrostatics, must weigh exactly the same as before. If it be alleged that, in blowing up the bladder, a portion of air would be introduced immediately from the lungs, and containing, therefore, a small admixture of carbonic acid gas, which is specifically lighter than the common atmospheric fluid; the additional weight, amounting scarcely perhaps to a grain, would be too minute to be detected by any of the jeweller's balances constructed in ancient Greece.

Physical Tenets of Aristotle.

The mutual opposition of the leading philosophical sects of antiquity had, in general, most fatally discouraged the application of mathematical reasoning to the system of the material world. The Academi-

Barometer.

cians, or the disciples of Plato, who cultivated geometry with ardour and brilliant success, were disposed to regard that science as a pure intellectual contemplation; and resigning themselves to the illusion of their lofty dreams, they turned with disdain from the investigation of individual facts and all the vulgar realities of life. The mind of Aristotle was of a more sober and practical cast; acute, profound, and discriminating, it ranged, with incredible industry, over an immense field of inquiry. That judicious philosopher recommended a careful and constant appeal to external observation, as the only sure ground on which to erect the structure of physics; but unfortunately his scholars neglected too much the study of mathematics, the most powerful instrument for conducting physical research. The precepts of Aristotle, though excellent in some respects, were hence in the sequel unproductive of any genuine fruit. On the contrary, the weight of his opinions, during a long course of ages, confined and repressed the efforts of human genius.

Modern Experimentalists.

It must be gratefully acknowledged, that the alchemists, styled also philosophers by fire, were the first among the moderns who dared to explore new paths of science. Their projects were, indeed, highly chimerical, but they had the merit at least of setting the example of investigating the properties of matter by actual experiment. They likewise formed associations among individuals, for the more effectual prosecution of such researches. Hence the origin of that obscure sect, known by the fanciful title of Rosicrucians, who sprung up in Germany, and insensibly spread their influence over the Continent. Those principles were afterwards transplanted into the matured soil of Italy, where philosophy, succeeding to the cultivation of letters, wore a more attractive garb. Baptista Porta, a Neapolitan nobleman, who flourished about the latter part of the sixteenth century, was especially distinguished by his zeal in promoting such pursuits. Having spent many years in travelling over Europe to gain information respecting natural objects, he invited a few individuals of a similar taste to assemble, at stated times, in his house, and assist him in making new experiments. These meetings, however, gave umbrage to the watchful jealousy of the clergy, and they were soon suppressed by a mandate from the Court of Rome. But the example was imitated in other parts of Italy, where the papal authority enjoyed less respect; and academies, for the promotion of natural science, were successfully instituted under the patronage of different princes, particularly those of the illustrious house of Medici.

Galileo.

In this ferment of inquiry, Galileo arose, a man fitted alike by the gifts of nature, and the lights of education, to be the founder of experimental science. His elegant genius was invigorated by the study of the Greek geometry; and he conceived the happy and prolific idea of employing that refined instrument to explore facts and combine the results. Archimedes, indeed, among the ancients, had anticipated this road of discovery, having most successfully applied the powers of geometrical analysis to the investigation of some parts of mechanics and hydrostatics. But his was a solitary instance, unheeded by succeeding ages. The ingenuity of Galileo prepared a complete revolution in science. By means of a few simple but striking experiments performed on the lagoons of Venice, he established the laws of motion, which he now transferred from the surface of our globe, to direct the revolutions of the heavenly bodies. The publication of his *Dialogues*, which unfold the right process of induction, and are not less distinguished by fineness of conception than beauty of diction, form a new era in the annals of philosophy. He was the first that attempted to ascertain the weight of air by actual experiment; and considering the nicety of the operation, and the rudeness of the instruments constructed at that period, he made a very tolerable approach to the truth. It had been known for many ages, that air is capable of being highly condensed; and Ctesebius of Alexandria had invented an engine, which, by the force of the sudden expansion of this compressed fluid, hurled missile weapons. This was afterwards improved into the wind or air-gun, which seems to have been not uncommon in Europe as early as the fifteenth century, though soon afterwards generally superseded in practice by the introduction of fire-arms. Galileo, being led by a different path from that pursued at present, set himself to examine the weight which air acquires by condensation. Having fitted a large copper vessel with a valve, he injected air into its cavity by means of a syringe, and then suspended it to a balance. The additional increase of weight being thus found, he opened the valve under an inverted glass receiver full of water, and measured, by the displacement of this liquid, the surplus quantity of air which had been injected into the copper vessel. He thence concluded that air is 400 times lighter than water, being about the double of the true estimate.

After he had, by such researches, acquired celebrity in the scientific world, Galileo accepted an invitation, with a very handsome appointment, from Cosmo de Medici; and devoting himself intensely to astronomical observations, aided by the telescope, which, from an obscure hint, he had recently constructed, yet occasionally unbending his mind with elegant recreation, he spent almost the whole of the evening of his life, at the villa of Arcetri, near Florence, in a style of comfort and even splendour. But, while occupied with those delightful pursuits—exploring the planetary phases—and discovering new worlds—he was for a moment recalled to his early studies, by an incident destined to form an epoch in the history of physical science. Some artisans, in the service of the Grand Duke, having been employed to construct a lifting or sucking pump for a very deep well, found, with equal surprise and vexation, that, in spite of all the pains they had taken in fitting the piston and valves, the water could by no effort be made to rise higher in the barrel than eighteen palms, or thirty-two feet. In this dilemma, they applied to Galileo for an explication of the cause of a failure so unexpected and perplexing. But the philosopher was not yet prepared to encounter such a discordant fact. The Aristotelian tenet of the impossibility of the existence of a void, was, at this period, universally received as an unquestionable truth. It had become a favourite axiom of the schoolmen, deceiving

Incidental failure of a Sucking Pump.

themselves—as Leibnitz did afterwards, in proposing his principle of *sufficient reason*—by the glimmer of a metaphorical expression, the *fuga vacui*, or *nature's horror of a void*. To create a vacuum, they gravely maintained, would require the hand of Omnipotence, transcending the utmost power of men or even devils. But Galileo, though borne along by the current of opinion, saw the necessity of at least modifying the general principle. Without questioning nature's abhorrence of a vacuum, he supposed the influence of this horror to be confined within certain limits, not exceeding the pressure of a column of water eighteen palms in height. This was evidently evading, rather than meeting, the difficulty proposed for his solution. Yet, in the last of his Dialogues, he actually mentions an experiment to ascertain this power or *virtu*, as he calls it, of a vacuum. A piston, exactly fitted into a smooth hollow cylinder, was rammed quite to the end, and this carefully shut up; then placing the cylinder in an upright but inverted position, successive weights were appended to the rod, till it was drawn from the close end, and pulled down. It may seem strange, that the Tuscan philosopher, after advancing so far, should have stopt on the verge of a great discovery. He had already weighed the air, and it was only another small step thence to infer the effect of its incumbent mass. But the atmosphere was still supposed to reach to the moon, and the pressure of columns of such enormous height seemed to mock all calculation, and overwhelm the imagination.* Yet, on reconsidering the subject, Galileo began to suspect the solidity of the explication which he had given; but it was now too late for him, in his advanced age, loaded with bodily infirmities, and dispirited by clerical persecution, to attempt any farther innovation in science. Recommending it earnestly to his friend and pupil Torricelli to resume the investigation, this illustrious precursor of Newton expired in 1642, the very year in which the English philosopher was born. His uniform kindness and urbanity rendered him extremely beloved; and his disciples, particularly Torricelli, Viviani, and Ricci, venerating his memory, caught the same taste, and followed similar pursuits.

Timid and imperfect Explication of Galileo.

Torricelli's famous Experiment.

Torricelli now conceived the happy idea of exhibiting the action of a pump on a contracted scale, by means of a column of mercury, which is nearly fourteen times heavier than water. This experiment he first communicated to his friend Viviani, who performed it with success in 1643; and he afterwards repeated and varied it himself. The method which he took brought very neatly under one view all the circumstances affecting the question. Having selected a tube about a quarter of an inch wide, and four feet long, he sealed one of the ends hermetically, or closed it under the flame of a lamp; he then filled the cavity of the tube with mercury, and applying his finger to the open end, he inverted it in a bason likewise containing mercury, though covered with a portion of water. The mercury instantly sunk to nearly thirty inches above the lower surface; but on raising the tube, till its orifice communicated with the layer of water, the mercury run all out, and the water now sprung up to the top, and occupied the whole of the cavity. It was thus proved, that the water and mercury are each supported by the same equipoise, which Torricelli, after some hesitation, at last concluded to be the pressure of the external atmosphere. He next converted the mercurial column into a form adapted for observation, by bending the lower end of the tube, and constructing what has since received the name of the *syphon barometer*. (*See fig.* 1. Plate XXXII.) Thus armed with a commodious instrument, he soon detected the variation of atmospheric pressure, which depends on the change of weather. These important results were published in the year 1645; but Torricelli did not live to enjoy the fame of his great discovery, for this most promising genius was snatched away by a putrid fever in the flower of his age.

The report of Torricelli's first experiments having been carried to France before he had ventured to draw his capital conclusion, set philosophers to speculate on the cause of such an unexpected fact. Descartes, with his usual rapidity and boldness of conception, did not hesitate, in his correspondence with Mersenne, to refer the suspension of the mercury in the tube at once to the pressure of the external atmosphere. But this influence appears not very consistent with his system, which assumed the existence of an absolute plenum, and only supplied the place of a void by the diffusion of subtile abraded particles of matter. He suspected also the accuracy of Galileo's estimate of the weight of the air, which he thought was scarcely appreciable by experiment.

Pascal's Experiments.

But, in the same country, the subject was now pursued with deliberate caution, and through all its details, by another genius of the highest order; one of the finest and most original that France has ever produced. Pascal had shown premature and extraordinary talents, which were encouraged by his father, a man of learning, who lived in habits of intimacy with the literati of Paris. The young philosopher happened to be residing at Rouen, in 1646, when he was informed of the famous Italian experiment. Having access, fortunately, to a glass-house, he resolved immediately to repeat the observations on a large scale. He had already suspected the justness of the principle, that "nature abhors a vacuum," and thought that the condensation and rare-

* This narrative, which marks so well the slow and timid steps whereby men, even of the highest intellectual endowments, usually advance in the search after truth, is drawn from the writings of Galileo himself. The carelessness of some authors in mis-stating facts, and imputing unworthy motives to those patriarchs of science who could not open their eyes all at once to the bright effulgence of day, deserves severe reprehension. We may remark, in passing, that M. Biot, who ranks now among the first mathematicians and philosophers in France, has not scrupled, in a recent bulky compilation on physics, to allege that Galileo only joked with the artisans who asked him the reason of the failure of their pump; that he had an idea of the true explication, but chose to keep his secret, and suffered it to die with him. Such a contemptible conduct would certainly have been a reproach to Galileo's acknowledged candour.

Barometer. faction of the air point to a different, or at least a modified conclusion. With a view to clear up this subject, Pascal performed a number of satisfactory experiments, of which we shall cite a few of the more striking, nearly in his own language, tinctured evidently with the prevailing opinions of the age: 1. Having fitted a piston to an open glass tube, and rammed it quite down, he applied his finger close to the lower end, and plunged the whole under water; then drawing back the piston, which was done with ease, the finger felt strongly and rather painfully attracted, while an apparent vacuity was formed above it, and continued to enlarge: but instantly on removing the finger, the water, contrary to its nature, darted up and filled the whole of the cavity. 2. A glass tube, about fifty feet long, sealed hermetically at one end, and filled with water, or rather red wine, as a more visible fluid, was inverted perpendicularly in a bason of the same. The liquid immediately subsided, leaving a vacant space of thirty-five feet; but, on gradually reclining the tube, the liquid rose again, and continued to mount, till it struck a sharp blow against the top of the glass. 3. A syphon, having one leg fifty-five feet high, and the other only fifty, being filled with water, and planted in two basons containing the same, such that the shorter branch had a perpendicular position, the water sunk in both to the same level, without being attracted, as usual in syphons, to the longer branch; but, on leaning the syphon back, the columns rose till they united at the top, and then the water began to flow towards the lower bason. The same experiment was also performed with mercury, the syphon having one leg ten feet, and the other only nine feet and a half in length, the mercury being found to divide itself into two columns, which continued suspended at an altitude of about thirty inches. 4. Having nicely fitted a piston to a long glass syringe, and pushed it down to the end, he immersed this in a bason of mercury, and held the tube in a vertical position; on gently drawing up the piston, the mercury closely followed it to the height of twenty-nine inches, but then stopt, leaving the piston to form above it an apparent vacuity. In this state, also, the syringe weighed exactly the same, whatever was the magnitude of the vacant space.

His cautious induction.

From these and other similar experiments, Pascal led his inductive process, with a degree of caution that might seem to border on timidity. He inferred that all bodies have a reluctance to a visible separation, or that nature abhors an apparent void; that this reluctance is exactly the same for a small as for a great vacuity; and that the force is limited, and exceeds not the pressure of a column of water thirty-three feet in height. He next ventured one step farther, and concluded, that this apparent vacuity was not filled by air lodged in the pores of the glass, or derived from external filtration; that it contained no subtile matter secreted from the atmosphere, and was not occupied by mercurial vapours or spiritous exhalations; in short, that a real and absolute vacuum had been formed.

Attacked by Nöel.

Pascal, then only twenty-four years of age, proposed to write a treatise on the subject of those inquiries; but thought proper, in the meantime, to publish a short abstract of it, which appeared in 1647, and involved him in a wretched controversy. Father Nöel, rector of the Jesuits' College at Paris, keenly attacked it, armed with all the miserable sophisms of the schools, and the absurd dogmas of the Romish church. He contended, that the space above the mercurial column was corporeal, because it was visible and admitted light; that a void being a mere non-entity, cannot have different degrees of magnitude; that the separation produced in the experiments was violent and unnatural; and he presupposed that the atmosphere, like blood, containing a mixture of the several elements, the fire and the finer part of the air were detached from it, and violently forced through the pores of the glass, to occupy the deserted space. To enforce these puerile arguments, the reverend Jesuit did not scruple to employ the poisoned weapon which his order has often wielded with deadly effect,—the hinting an oblique charge of heresy. This rude attack only roused Pascal, and disposed him boldly to throw off the fetters of inveterate opinion. He began to perceive that "abhorrence" cannot, in strict logic, be applied to nature, which is a mere personification, and incapable of passion; and was inclined, by degrees, to adopt the clear disembarrassed explication of Torricelli, referring the suspension of the mercurial column to the pressure of the external atmosphere. In stating this conclusion, he makes some remarks which would deserve the serious attention of philosophers in the present age. "When the weakness of men is unable to find out the true causes of phenomena, they are apt to employ their subtlety in substituting imaginary ones, which they express by specious names that fill the ear, without satisfying the judgment. It is thus that the sympathy and antipathy of natural bodies are asserted to be the efficient and unequivocal causes of several effects, as if inanimate substances were really capable of sympathy and antipathy. The same thing may be said of the antiperistasis, and various other chimerical causes, which afford only a vain relief to the avidity of men to know hidden truths, and which, far from discovering them, only serve to conceal the ignorance of those who invent such explications, and nourish it in their followers." These remarks, equally judicious and profound, are the more striking, since Lord Bacon, while he proposed to reform and new-model the whole structure of human learning, yet complied with the taste of his age in retaining much of the jargon and barbarous distinctions of the schools.

Pascal's decisive Experiment.

But Pascal did not rest satisfied with mere reasoning, however strictly conducted; and he soon devised an experiment which should palpably mark, under different circumstances, the varying effects of atmospheric pressure. It occurred to him, that, if the mercury in the Torricellian tube were really supported by the counterpoising weight of the atmosphere, it would be affected by the mass of superincumbent fluid, and must therefore partially subside in the higher elevations. He was impatient to have his conjecture tried in a favourable situation, and, in November 1647, he wrote a letter communicating those views to his brother-in-law, Perier, who filled an office of considerable trust in the province, and commonly resided at Clermont in Auvergne, in the immediate vicinity of the Puy de Dôme, a lofty coni-

cal mountain, which rose, according to estimation, above the altitude of 500 toises. Various avocations, however, prevented that intelligent person from complying with his instructions, till the following year. Early in the morning of the 19th of September 1648, a few curious friends joined him in the garden of a monastery, situate near the lowest part of the city of Clermont, where he had brought a quantity of mercury, and two glass tubes hermetically sealed at the top. These he filled and inverted, as usual, and found the mercury to stand in both at the same height, namely, 26 inches and $3\frac{3}{4}$ lines, or 28 English inches. Leaving one of the tubes behind, in the custody of the subprior, he proceeded with the other to the summit of the mountain, and repeated the experiment, when his party were surprised and delighted to see the mercury sink more than three inches under the former mark, and remain suspended at the height of 23 inches and 2 lines, or 24.7 English inches. In his descent from the mountain, he observed, at two several stations, that the mercury successively rose; and, on his return to the monastery, he found it stood exactly at the same point as at first. Encouraged by the success of this memorable experiment, Perier repeated it on the highest tower of Clermont, and noted a difference of two lines at an elevation of 20 toises. Pascal, on his part, as soon as the intelligence reached him at Paris, where he then chanced to be, made similar observations on the top of a high house, and in the belfry of the church of St Jacques des Boucheries, near the border of the Seine; and so much was he satisfied with the results, that he proposed already the application of the barometer for measuring the relative height of distant places on the surface of the globe.

The investigation of the existence and effects of atmospheric pressure was now completed, and it threw a sudden blaze over the whole contexture of physical science. The fame of the experiments performed in Italy and in France, quickly spread over Europe. Yet such is the force of habit and early prejudice, that, after the first moments of surprise and confusion, few of the learned at this period had the courage to open their eyes to the light which had so unexpectedly burst upon them; but, secretly cherishing their inveterate notions, they sought to comfort themselves, by starting a variety of captious objections. Father Mersenne, though a man of some abilities, conceived that suction was occasioned by certain hooked particles dispersed through the atmosphere, which laid hold of any fluid in contact with them, and drew it towards the general mass. Father Linus, plunging still deeper in mysticism and absurdity, gravely proposed the *funicular hypothesis*, which attributes the suspension of the mercurial column to the agency of certain small invisible threads. But others of the clergy attacked Pascal with envenomed bitterness. The Jesuits of the college of Montserrand scrupled not, in their public theses, to pervert his expressions, and even contest the originality of his experiments. The philosopher was justly incensed at their base conduct; and those repeated provocations served, no doubt, to give a keener edge to his wit, when he afterwards directed it with such overwhelming energy against that insidious and formidable order of priesthood. He composed in 1653,

Opposition which it experienced.

though they were not published till after his death, two short treatises, *On the Equilibrium of Liquors*, and *On the Weight of the Mass of Air*, remarkable for their neatness, perspicuity, and lucid order. The laws of the equilibrium of fluids are there beautifully deduced from a single principle, which suggests a variety of original views and admirable remarks. In those tracts, he likewise gives a description of the Hydraulic Press, a most useful and powerful machine, which has lately been revived in this country, and considered as a new invention.

Discovery of the Air-pump by Güricke.

A similar discovery, which was made about the same time in Germany, came seasonably to support the triumph of innovation. Otto Gürické, a wealthy magistrate of Magdeburg, who amused his leisure by constructing pieces of mechanism, and instituting curious physical inquiries, finding that the belief in the impossibility of a vacuum, with other scholastic tenets, was on the gradual decline, had the boldness to conceive that the forming of a void was a task perhaps within the reach of human ingenuity. Fired with the idea of accomplishing what for ages had been deemed unattainable, he directed all his efforts to compass that end. In his first trials he failed, as might be expected; but, by perseverance, he was enabled to surmount every obstacle. Having filled a wooden cask with water, he attempted to extract this again, by means of a small sucking pump, introduced at the bottom of the cask, and worked vigorously by three stout men; a hissing noise was heard like that of boiling water, the air entered from above through the interstices of the wood, and the water flowed out. The more effectually to exclude the air, he next took a smaller cask, with a sucker attached to it, and placed it within a larger one, having filled up the space between them with water. On working the pump as before, the water was forced through the pores of the wood into the inner cask, but none was extracted by the action of the piston. Foiled in these attempts with wooden casks, he had recourse to a copper ball, to the under part of which he screwed an inclining sucker; and, with this apparatus, he at last succeeded in extracting the air. He continued the operation, till no farther portion of air was perceived to issue from the vent. On opening the cock again, the air rushed into the cavity of the ball with violence; and the same effect took place, with scarcely any diminution of power, after an interval of a day or two. The construction of the machine was afterwards rendered more perfect, by substituting a large inclined metal sucker, with its joints secured by immersion in water.

Such was the origin of that most valuable addition to philosophical apparatus—the air-pump, which long retained its earliest rude and simple form on the Continent. By help of this new and powerful instrument, Gürické was enabled to perform some interesting and very important experiments. One of these, which demonstrates in a very striking way the pressure of the atmosphere, has been since deservedly styled the Magdeburg Experiment. It was performed with two hollow copper hemispheres, closely fitted together, and the air exhausted from their cavity. This singular experiment Gürické had the honour of exhibiting, in the year 1654, before the princes of the

empire and the foreign ministers, assembled at the diet of Ratisbon. The force of two teams, each consisting of a dozen of horses, made to pull in opposite directions, was found insufficient to separate the hemispheres. It was now that the Burgomaster of Magdeburg heard, for the first time, of Torricelli's great discovery, and the intelligence must have appeared quite delightful to him, who, by a path so different, had yet arrived at a similar conclusion.

After his return from this splendid assembly, Gürické pursued at home various pneumatical researches. He showed the diminished pressure of the atmosphere at an elevation above the surface, by means of a hollow ball fitted with a stop-cock; having carried this to a height, a portion of the contained air rushed out on turning the cock; but when it was brought down again and opened, the same measure of air apparently flowed into its cavity. He actually weighed the air, by ascertaining, by a nice balance, the loss which a large bottle sustained on being exhausted, and found that air is 970 times lighter than water, a very near approximation, if allowance were made for the residuum of air still left in the bottle. He was the first who proposed the *Statical Balance* for measuring the variations of atmospheric density, consisting of a hollow glass ball about a foot in diameter, hermetically sealed, and freely suspended in the air, to indicate by its different buoyancy the changes which take place in the gravity of the external fluid.

But Gürické took great pleasure in a huge water barometer erected in his house. It consisted of a tube above thirty feet high, rising along the wall, and terminated by a tall and rather wide tube hermetically sealed, containing a toy, of the shape of a man. The whole being filled with water, and set in a bason on the ground, the column of liquid settled to the proper altitude, and left the toy floating on its surface; but all the lower part of the tube being concealed under the wainscoting, the little image, or weather-mannikin, as he was called, made its appearance only when raised up into view in fine weather. This whimsical contrivance, which received the name of *anemoscope*, or *semper vivum*, excited among the populace vast admiration; and the worthy magistrate was in consequence shrewdly suspected by his townsmen of being too familiar with the powers of darkness.

The taste for experimental science was about this time introduced from the Continent into England. The great struggle for the security of private rights had called forth the national energy, and its triumphant success had infused among all classes of men a spirit of boldness and enterprise most favourable to the reception of the new philosophy. The parliamentary commissioners, by removing the more violent and bigoted members of the universities, contributed, on the whole, to encourage a more liberal tone of thinking in those opulent seminaries. Near the close of the civil war, and during the vigorous administration of Cromwell, the philosophy by experiment found some proselytes at last among the cloisters of Oxford, where the mass of antiquated opinions had lain so long embalmed and protected by religious awe. A small association was there formed, for combining together the efforts of individuals in the prosecution of such inquiries; and the fruits of this mutual compact were afterwards visible in the composition of various philosophical works. But the Restoration, by which the nation, in a burst of inconsiderate loyalty, surrendered the privileges which it had purchased with torrents of blood, threw the government of the universities again into the hands of men decidedly hostile to the very shadow of improvement. Experimental science withdrew to a more congenial soil, and sought shelter and support in the wider scope of the capital. The college founded by the munificence of Sir Thomas Gresham, for the benefit of the citizens of London, though now unfortunately sunk in absolute neglect, had the merit of first extending its protection to the pursuits of inductive philosophy. It produced a succession of professors, eminent in mathematical learning, which is so closely allied with experimental research. A more extensive association was accordingly formed in London, which regularly met at the apartments within the Exchange, and was afterwards, at the suggestion of Oldenburg, the resident from the city of Hamburg, and in imitation of the foreign academies, constituted by charter into the Royal Society. Such was the humble beginning of that illustrious body, and such was all the countenance it received from a needy and profligate government. The institution, however, proved at first eminently useful, by the influence it had in directing the public opinion, and the shelter it afforded to experimental philosophy against the jealousy and declared hostility of the clerical and scholastic seminaries. The union of rank, or wealth, or talent, though still very limited in its range, bestowed a degree of lustre on the infant society, that was quite necessary for its defence against the attacks of ignorance, and the mining of bigotry.

One of the most active members of the Royal Society was Mr Boyle, who, having become acquainted with experimental researches in the course of his travels, devoted, after his return home, his time and his fortune to such calm but engaging pursuits. In this occupation, he derived the most essential aid from Dr Hook, whom he had the discernment to engage as his assistant,—the most skilful mechanician, and the best practical philosopher, of the age. The same ingenious person was likewise employed as operator to the society, and undertook to produce at each meeting some new experiments for the instruction and entertainment of the members. One of the favourite subjects was to exhibit the properties of the atmosphere. Dr Hook, at the instance of Mr Boyle, had given a more convenient form to the air-pump, and had materially improved its construction, especially by the application of oil to the joints and valves. With this improved machine, a more perfect vacuum was procured than Gürické had obtained; and the English philosophers were thus enabled to perform a variety of delicate and interesting experiments, which extended the influence of the original discovery.

In those early meetings, too, of the Royal Society, the suspension of the mercury in the Torricellian tube had still the attraction of novelty. The famous

Barometer.

Italian experiment, as it was called, was frequently repeated and varied in the presence of a few of the more assiduous members, who, though delighted with the exhibition, continued to reason and to doubt concerning the cause of the phenomenon. These doubts acquired new force from a singular experiment which the celebrated Huygens some years afterwards communicated, during a visit he made to London. Having filled a glass tube eighty inches long with mercury, and carefully expelled whatever air was lurking about the sides, he gently inverted it, as usual, in a bason; when the mercury notwithstanding remained still hanging from the top of the tube, and did not subside to the proper height, till it was struck with a slight blow. This anomalous fact appeared then extremely puzzling. The experiment, indeed, requires great nicety and address on the part of the operator, and evidently depends on a concurrence of circumstances which have not yet been sufficiently explained. There can, at present, exist no doubt that this extraordinary suspension of the mercury is occasioned by its obstinate adhesion to the inside of the tube, which, in the process of purging the air, becomes probably lined with a very thin film of mercurial oxyd. But Huygens, who had embraced the leading principles of the Cartesian philosophy, was inclined to draw a very different conclusion. He thought that the fact proved the existence of another fluid, besides the atmosphere, and one possessed of such extreme subtlety and power, as to be capable of permeating the grosser bodies. In ordinary cases, this fine ethereal substance might be supposed to escape through the pores of the glass, and leave the mercurial column to the mere pressure of the atmosphere. Such was the unfortunate introduction of that ideal being—an æther—into experimental science, which it has continued to infest with mysticism, and to dazzle with a false glare. Similar notions are perpetually renewed by a certain class of superficial inquirers, and have exercised a visible and most pernicious influence in retarding the progress of sound philosophy.

Huygens's Experiments.

Cistern Barometer.

It was soon perceived, that the syphon barometer of Torricelli has a disadvantageous form. Both branches of the tube being supposed of the same width, the mercury must evidently sink as much in the one as it will rise in the other; so that the variations in the height of the column are thence reduced to half the true quantity. A small bason, or semicircular wooden box, to hold the surplus mercury, was therefore attached to the frame of the instrument; and this construction, with very little change, was adopted, during the course of a century, by the makers of the ordinary barometer. But the syphon barometer itself was afterwards materially improved by having its lower branch blown into a wide bulb for holding the charge of mercury. (*See fig.* 2. Plate XXXII.) This form of the barometer is not quite accurate, owing to the smallness and unequal shape of the round bulb; but being very convenient for carriage, it has grown into general use, at least for the cheaper and more common sort of instruments.

Barometer of Descartes.

As soon as the barometer came to be regarded as a weather-glass, ingenuity was set at work to devise the means of enlarging its scale of variations. Descartes first proposed a simple method for effecting that object, by combining a mercurial with a water barometer; which arrangement, through subject to imperfection, has led to many of the subsequent improvements. (*See fig.* 4.) He directed two short barometric tubes to be cemented, the one into the bottom, and the other to the neck of a phial; or, still better, that the tubes should be joined, by the flame of a lamp, to the opposite ends of a wide and regular cylinder. The lower tube, and a portion of the cylinder, were then to be filled with mercury, and above it was to be introduced pure water, reaching to the top of the upper tube, and there sealed close. When this compound tube was inverted in a bason of mercury, it is evident that the columns both of mercury and of water would sink, till their joint pressure became just equal to the superincumbent weight of the external atmosphere. But the variation of this weight would afterwards be indicated chiefly by the large motion of the water; since the mercurial column, spreading out above into a broad surface, must, in any case, experience a very slight difference of altitude. Thus, suppose the cylinder to have eight times the diameter of the upper tube, or a section sixty-four times greater, mercury being 13.6 times denser than water: For each inch of increase of altitude which the ordinary mercurial column gains, the top of the water would be raised in the tube 11.4 inches, its own rise being 11.18 inches, and that of the wide mercurial cylinder only .18 of an inch, yet equal in pressure to 2.4 inches of water. But Descartes, generally satisfied with mere theory and speculation, did not live to see his construction of the barometer carried into effect; and Chanut, the French resident at Stockholm, to whom he had imparted his views, met with such difficulty in the execution of the project, that, after some fruitless attempts, he abandoned it altogether.

Huygens's Double Barometer.

Huygens was more fortunate; and succeeded, by dint of perseverance and skill, in constructing the Cartesian barometer. But he had the mortification to find that, in spite of all the pains he could take, the water, after it was relieved from the pressure of the atmosphere by the sealing up of the tube, constantly discharged a portion of air, which collected at the top, and by its elasticity depressed the compound column below its due altitude. Convinced that this source of imperfection is irremediable, he sought to rectify the construction of the instrument, and produced his *Double Barometer;* a form of combination frequently used, especially when the object is rather to make the variations very sensible than to obtain delicate results. (*See fig.* 5.) He joined a barometric tube of the usual length by the flame of a blowpipe, to two wide cylinders, the one sealed at the top, and the other annexed likewise hermetically to a tall and narrow tube, open at its extremity; he then bent the thicker tube a little above the lower cylinder, and brought the two branches to be parallel. The instrument being thus formed, he filled the first branch with mercury, and introduced above, in the second branch, some liquid of comparative lightness. Alcohol would, in this respect, answer extremely well, if it were not so liable to waste by evaporation.

An alkaline lye, or the deliquiate salt of tartar, which also readily admits of being coloured, was, therefore, on the whole, preferred.

The principle of this construction is evidently the same as in that of Descartes; but the vacuum lying contiguous to the mercury itself, can have no admixture of disengaged air or of aqueous vapour. Since the cylinders are made very much wider than the bore of the annexed tube, the variation of pressure will be produced almost entirely by the change of altitude which the alkaline liquor undergoes, the mercury suffering only a very minute alteration of ascent or descent. The divisions of the ordinary scale will be about tenfold enlarged, if a section of each cylinder should exceed twenty times that of the tube in which the liquor plays.

Its advantages and defects.

A barometer of this construction has decided advantages with respect to the extent of its changes, but still it is not exempt from considerable defects. The moisture on the inner surface of the cylindrical reservoir increases the adhesion of the mercury, and retards its movements. But a much greater source of error proceeds from the influence of heat in extending the volume of liquor contained in that reservoir, and rising into the narrow stem. This instrument, therefore, to a certain extent, blends the indications of the barometer with those of the thermometer, which are essentially different, and can seldom accord.

Hook's Double Barometer.

About the same period, Dr Hook likewise proposed a double barometer, of a similar construction. He afterwards resumed the subject, and with a view to correct the defect of the former arrangement he produced, in 1685, an instrument of a more complex form, but very ingeniously conceived. (*See fig.* 6.) To the upper end of the open stem, he joined a third cylinder of the same dimensions as the two former, but tapering away to a fine orifice at the top. The principal tube being filled as usual with mercury, extending to occupy the bottoms of both the connected cylinders, he introduced a liquor immediately over the mercury in the second cylinder, rising partly into the stem; above this, again, he poured another liquor specifically lighter and differently coloured, filling up the rest of the stem, and mounting into the third cylinder. By this artificial and delicate combination, the mercury is left perfectly stationary, and all the movements corresponding to the changes of atmospheric pressure, are performed by the counterpoising liquors, and marked by their line of mutual separation. Since the stem or narrow tube remains constantly full, the variation of its pressure must depend on the different proportions of its length occupied by the two fluids. If the weight of external atmosphere should, for instance, increase, the denser liquor will rise, and consequently cause the lighter liquor to contract its column. The action of this compound barometer, being thus produced merely by the difference of the gravity of the two fluids, might, therefore, be augmented indefinitely. Suppose the liquid resting on the mercury to be pure water, and the superincumbent liquid to be olive oil, which is about one-twelfth part lighter; the scale would be enlarged no less than one hundred and sixty-three times, or an alteration of one-tenth in the altitude of the common mercurial column, would be marked by a motion through 12×1.36 inches, or 16.3 inches. But such a vast enlargement of the scale is far greater than would ever be desirable in practice. It were better, therefore, to introduce next the mercury some fluid which is denser than water. If oil of sassafras were combined with oil of oranges, the divisions of the scale would be augmented only sixty-eight times, and consequently the whole range might not exceed ten or twelve feet. Those oils, however, would move rather sluggishly, especially in cold weather, and might, from their incessant shiftings, during a lengthened period, become insensibly mixed. On the other hand, fluids of distinct characters are seldom free from chemical action; they expand differently with heat, and by coating with other traces the inside of the tube, they are the more apt to retard the motion of the column. In general, the advantage of any very great augmentation of the scale is counterbalanced, as the fluids then work by irregular starts; and the instrument loses in delicacy whatever it has gained in extent of action.

Another method of augmenting the variations of the barometer was invented by the same fertile genius, which has the advantage of uniting great simplicity with tolerable accuracy. (*See fig.* 7.) Resuming the syphon barometer, he made a small float of iron or glass to rest on the exterior surface of the mercury, and suspended by a slender thread passed round a small wheel or cylindrical axis that carried an index. Though the varieties of the height of the mercurial column are in a tube of this form, reduced to half the ordinary measure; yet, from the great length of the index compared with the diameter of its axis, the divisions on the circumference of the circle in which it travels are much amplified. The little machinery being concealed within the frame of the instrument, the index only is brought into view, protected by a circular plate of glass. Thus fitted up, the whole forms rather a handsome piece of furniture. The *Wheel Barometer*, as it is called, has long maintained its reputation among ordinary observers.

Wheel Barometer.

Inclined Barometer.

A very simple mode of enlarging the divisions of the barometer is commonly ascribed to Sir Samuel Moreland, the same person who had invented, or perhaps only revived, the *Speaking Trumpet*. (*See fig.* 8.) It consisted in merely bending the upper part of the tube into a very oblique position. By this plan, however, the scale, which depends on the perpendicular altitude, cannot be augmented beyond three or four times, without incurring evident risk of inaccuracy. This instrument is called the *Inclined* or *Diagonal Barometer*. The form has been sometimes varied by the fancy of artists, who, repeating the inclination of the tube, have occasionally given the upper part a zig-zag appearance.

Square Barometer.

The most ingenious barometer, filled with mercury only, and yet admitting a scale of any extent, was invented by Cassini and by John Bernoulli, who first gave the description of it in 1710. (*See fig.* 9.) A wide cylinder is annexed to the top of the main tube, at the bottom of which there is joined at the right angles another long and narrow tube. The mercury, in ascending or descending within the wide cylinder

Barometer.

must, therefore, run along this horizontal tube. If that cylinder have a diameter only four times greater than the bore of the tube, the scale of variation will be augmented sixteen times. This instrument is, from its shape, called the *Square Barometer*. It is not found in practice to answer so well as the theory might lead us to suppose. The mercury creeps along the horizontal tube with difficulty, and by desultory advances; and these irregularities increase, as it becomes, from its motion and exposure, covered with dust and partial oxidation.

Conical Barometer.

The simplest of all the barometers, with an enlarged scale, and, at the same time, one of the most ingenious, is the *Conical* or *Pendant Barometer*, invented and described in 1695, by Amontons, a French philosopher, who being afflicted with total deafness, in consequence of a fever in his infancy, had devoted himself to mechanical contrivances. (*See fig.* 3, Plate XXXII.) This instrument consists merely of a tube, four feet or more in length, with a bore narrower than ordinary, and tapering regularly to the top. The width at the bottom must hardly exceed three-twentieth parts of an inch, while near the top it may be contracted to about one-tenth. A column of thirty-one inches of mercury being introduced, the tube is gently inverted and held perpendicular; the cohesion of such a narrow column is sufficient to prevent it from dividing and admitting the air, unless it be shaken; but overpowering the atmospheric pressure, it descends till it has contracted into the equiponderant altitude, by passing into a wide part of the tube. To obtain equal divisions on the scale, it is necessary that the tube should have an uniform taper. The most accurate construction of a barometer of this kind is, therefore, attained by forming together two tubes that have even but unequal bores, the longer and narrower one being uppermost. If the width of the upper tube were supposed to be to that of the under one as two to three, the scale would be enlarged three times, since, by descending three inches from the top, and consequently two at the bottom, the column would suffer a contraction of one inch in height.

This species of barometer is thus recommended by its simplicity and its ample range. But the bore of the tube being indispensably narrow, the mercury moves with difficulty, and resists the impression of minute changes of external action. When the conical shaped tube is retained, the instrument is liable to some inaccuracy from the influence of the cohesion of the mercury, which varies with the diameter of the column in different parts of the tube.

Amontons likewise proposed another form of barometer, in which the mercurial column is subdivided among several short connected branches. (*See fig.* 10.) Suppose the instrument were to have only the third part of the usual height; the first, third, and fifth branches enlarged above and below into very short cylinders, are filled with mercury; and the second, fourth, and sixth branches, which may have their bores narrower, are occupied with some light fluid, or simply with air. If the external pressure should suffer any diminution, the three mercurial columns which produce the counterpoise, will each descend and push up the last fluid of the series by their combined effects. It is evident, that, by multiplying those branches, the barometer will have its altitude proportionally reduced. But this construction, though specious in theory, is found to have no practical advantages. The instrument is, from its complication, very difficult to construct; its motions are sluggish, owing to the multiplicity of tubes, and the conjunction of fluids, and they are subject to derangements from the variable influence of temperature. It has, therefore, been generally abandoned.

Sectoral Barometer.

These different forms of the instrument have been variously modified, and often brought forward with claims of novelty. We may notice, however, the *Sectoral Barometer* proposed by Magellan, in which the mercury is always made to rise to the same high point of the tube, by drawing this less or more aside from the vertical position. The arc they described will indicate the deviation from the perpendicular, and consequently the actual descent of the mercury. But the difference between the vertical and the oblique line is not measured by the inclination merely; it is proportioned to the versed sine of this angle, or nearly to the square of the arc. The advantage of this mode of observing is, therefore, best perceived in small variations of the mercurial column. In the hands of a skilful observer, the best and most accurate barometer, after all, is that of the original construction, with a tube rather wide, and a broad cistern. To apply minute divisions, is decidedly preferable to any enlargement of the scale. The measuring of such divisions has been since rendered extremely easy, by the adaptation of the differential scale—a most valuable contrivance proposed by Vernier, early in the seventeenth century, but strangely neglected long afterwards. This delicate appendage being once adopted, it became the more desirable to improve the sensibility, and regulate the correctness of the indications of the barometer.

Effect of Moisture within the Barometric Tube.

The first object was carefully to cleanse the mercury, and to expel any portions of air or moisture adhering to the inside of the tube. The influence of aqueous vapour in depressing the mercurial column had been observed by Huygens; but other more evaporable fluids were afterwards found to occasion, by their presence, a still greater derangement. Homberg having, about the year 1705, washed a tube with alcohol, to remove the impurities from its internal surface, remarked that the mercury introduced into it stood an inch and half lower than usual; a depression which this ingenious chemist was disposed to attribute to the elasticity of the spiritous exhalations collected above the mercurial column; though other academicians, and Amontons among the rest, misled by their Cartesian prejudices, sought to ascribe the effect to the different sized pores of the glass. These anomalies were removed, by heating or rather boiling the mercury in the tube, till it was completely purged of air and moisture, and brought into close contact with the inside of the tube. But a new fact occurred which long puzzled the mechanical philosophers. The tube

Barometer. Luminous Barometer.

of a barometer, which had been filled with more than usual care, was observed to exhibit a luminous appearance, when moved or slightly agitated in the dark. This curious phenomenon gave occasion to multiplied and prolonged controversies; it was attributed to the subtile matter of Descartes, or ascribed to a native phosphorescence, or a latent fire inherent in the mercury. Our countryman, Hauksbee, in the year 1708, gave the first rational explanation of the fact, by referring it to electricity, which he had just begun to cultivate as a distinct science. It resembles exactly, indeed, the experiment of the exhausted flask, in which an electrical current flashes with a diffuse lambent flame, like the *aurora borealis*, or the *northern streamers*. The friction of the mercury against the inside of the tube excites electricity, while the vacuity, or rather the very attenuated vapour, in which the supposed fluid plays, facilitates its expansion. When the vacuum is rendered very perfect, by the careful and accurate boiling of the mercury, the lambent flashing ceases, for want of a fine medium to conduct and disperse the electrical influence.

Effect of the width of the Tube.

The next point to which experimenters were led to direct their attention, was the effect of the width of the tube on the altitude of the mercurial column. Plantade, a lawyer at Montpellier, appears to have been one of the first who remarked that the mercury stands always lower in narrow tubes. This fact he communicated about the year 1730 to Cassini, who was then occupied in the south of France, with carrying on the great trigonometrical survey. But the discrepancies observed by Plantade being unfortunately confounded with other collateral circumstances, were for a time overlooked. In tubes having a narrow bore, the depression of the mercury, however, is very considerable, as may be readily perceived in a small glass syphon, of which the one branch is about half an inch in diameter, and that of the other branch less than the tenth of an inch. Thus, if the narrow tube had a width of only the thirteenth part of an inch, the depression of the mercury would amount to half an inch, which is about the third part of the elevation to which water in similar circumstances would be raised by capillary action. This effect has not been sufficiently examined, but it appears to result from the attraction of the particles of the mercury to each other exceeding their attraction to the surface of the glass. Mercury, in contact with glass, therefore, tends to a spherical form, and always assumes a convex surface within a clean tube. Water and other liquids again manifest an opposite character, the mutual attraction of their particles being less than their adhesion to glass. Accordingly, they spread along a vitreous surface, instead of collecting into drops; and in narrow tubes they mount above the level, and invariably have a concave termination. If the bore be so small as to be reckoned capillary, the depression of mercury is, like the elevation of water, inversely as the diameter; but when the bore has a considerable width, the quantity of depression, depending on the curvature of the surface of the mercury, diminishes proportionally faster, and follows nearly the inverse duplicate ratio of the diameter. But on the subject of capillary action, we expect, with no small degree of impatience, to see a paper which was very lately communicated to the Royal Society of London, by Mr Ivory, of the Military College at Sandhurst, one of the most original and profound mathematicians that our island has had the honour to produce.

Pure Mercury has always a convex surface.

The influence of the predominating attraction of the particles of mercury to themselves, above their adhesion to the sides of a glass tube, has not been considered with so much attention as it demands. Nothing is more common than to remark that the mercury in the barometer is in the act of rising, if it show a convex surface, but about to fall, if it should appear concave. Now, the top of the mercurial column must always remain convex, if the barometer be properly constructed, the tube perfectly clean, and the mercury purged of all impurities. But if the inside of the tube be any how soiled, whether covered with humidity or stained with mercurial oxyd, the metallic fluid will adhere so obstinately to the glass, as to lose its convexity, and to subside into a flat surface, or even sink into a concavity, like water and other liquids. Hence the danger of boiling the mercury too long in the tube, as it becomes partially oxydated, and the thin crust so formed not only suspends the column higher, but obstructs the freedom of its motion. The same effect is produced by greasing the inside of the tube. Some respectable authors, from not attending to these facts, have hastily inferred that the convex appearance which mercury assumes in the barometer was merely accidental, and consequently removed by a more complete boiling and purification.

Quantity of depression in different Tubes.

In the case of tubes having wide bores, the depression of the mercurial column may, without any sensible error, be disregarded. According to the accurate experiments made by Lord Charles Cavendish, and published by his son, the celebrated Mr Cavendish, the quantity of depression is only the 200th part of an inch in a tube of 6-10ths of an inch in diameter, the 28th part of an inch in a tube of 3-10ths diameter, and the 15th part of an inch in a tube of 2-10ths diameter. Wide tubes ought, therefore, to be preferred in the construction of barometers, both on account of the facility with which the mercury moves in them, and the smallness of its depression. The only circumstance to overbalance these advantages, would be the necessity and inconvenience of having a very large cistern. A quarter of an inch may be reckoned a good width of tube, and the corresponding depression is only the twentieth part of an inch.

Application of a leathern Bag.

In the syphon barometer, if both branches have the same diameter, the action is exerted on opposite sides, and, therefore, the effect of depression becomes entirely lost. For accurate purposes, this original form of the instrument has been again resumed, and the inconvenience arising from the large variation of the lower level entirely obviated by an ingenious contrivance introduced about forty years since. This consists in the application of a leathern bag, instead of a wooden or ivory cistern, to hold the surplus mer-

cury. Besides the barometric tube, there is placed adjacent to it another short one of the same width, communicating with the mercury contained in the bag, which being pressed by turning a screw below, is, at each observation, brought exactly to the same mark. The external atmosphere readily acts through the substance of the leather, but the mercury, from the powerful cohesion of its own particles, cannot be squeezed through the pores of that casing without violent compression. The addition of a bag within a cylindrical box, omitting the lower tube, likewise renders the barometer easily portable; since, for safe carriage, the mercury can be screwed up tight, to fill the whole cavity of its tube, but, on turning the screw again, the column will subside and rest on a broad base.

Effect of Heat on the Barometer.

The last object which required nice observation, was to estimate the effect of heat in dilating the mercury, and consequently increasing the altitude of the equiponderant column. This correction could not be made with any sort of accuracy previous to the application of the thermometer, which, though invented half a century earlier than the barometer, was yet more than another half century in arriving at perfection. Hero, a mechanical philosopher, who flourished at Alexandria about 130 years before Christ, has described in his *Spiritalia* a sort of huge weather-glass, in which water was made to rise and fall by the vicissitudes of day and night, or rather the changes of heat and cold. This machine had for ages been overlooked, or merely considered in the light of a curious contrivance. But Sanctorio, the inventor of the famous statical balance, a very learned and ingenious Italian physician, who was long professor of medicine in the university of Padua, and had laboured to improve his art by the application of experimental science, reduced the hydraulic machine of Hero into a more compendious form, and thus constructed, about the close of the sixteenth century, the instrument since known by the name of the *air-thermometer*, which he employed with obvious advantage to examine the heat of the human body in fevers. Some years afterwards, a similar instrument was contrived, perhaps without any communication, by Drebbel, a very clever and scheming Dutch artist, who visited London in the reign of James I., and introduced the knowledge of that instrument into England.

Invention of the Thermometer.

But this air-thermometer was evidently of the same nature with what has been since called the manometer; it could measure only the dilatation or augmented elasticity of the air confined within its bulb, whether occasioned by heat or the diminution of external pressure. It was, therefore, considered merely as a weather-glass, indicating the state of the atmosphere; nor could its blended impressions, which might separately affect both the thermometer and barometer, be then distinguished. Had it been more closely studied, it must have led, by another path, to the discovery of the latter. But those irregularities to which the air-thermometer was hence subject appear to have created such doubts respecting the accuracy of the instrument, as occasioned its being neglected long afterwards.

Florence Glass.

The same country, however, which had given birth to the thermometer, began its improvement. After the principle of the barometer was established, the members of the Academy del Cimento, founded at Florence in 1657, and supplied with liberal funds by the Grand Duke of Tuscany, had, among other interesting physical researches, resumed the application of the thermometer; and instead of air, they substituted alcohol or spirit of wine, another very expansible fluid not affected by pressure, while they attached to the tube a scale graduated on a regular plan, though directed by no very precise measures. The instrument so constructed, but somewhat varied in its form, being copied by Italian artists, was dispersed over Europe under the name of the *Florence Glass*. From its careless execution, however, in the hands of itinerant venders, this thermometer, or rather thermomoscope, appears never to have obtained an established reputation.

Attempts to obtain a Standard.

The great object was to bring thermometers to an exact correspondence. It was expedient, therefore, not only to select a proper fluid, but to adopt an uniform and consistent scale. Alcohol, linseed oil, and mercury, had been successively tried. The graduation was at first drawn from the temperature of cellars and deep caves, which, indicating the natural heat of the globe, had long been considered invariable; but more enlarged experience discovered the inaccuracy of that supposition, and showed the mean temperature to be materially modified by the latitude of the place, and its elevation above the level of the sea. Congelation, or rather the inverted process, the thawing of ice, or the melting of snow, was then found to remain fixed; a most important fact, which had been first noticed by Güricke, but overlooked till a considerable time afterwards. A stationary point was hence obtained, from which to commence the thermometer scale. But different modes were pursued for determining the divisions.

Amontons.

Amontons, reverting to the air-thermometer in spite of its acknowledged defects, found that the elasticity of air compressed in the bulb, and able at the temperature of melting snow to support a column of mercury fifty-four inches high, was capable of raising this to seventy-eight inches, at the heat of boiling water; and he seemed contented in framing a rude standard, with merely dividing the intermediate space into inches and half-inches.

Newton.

But about the same, or nearly at the beginning of the eighteenth century, Newton himself cast a keen though rapid glance on the subject of heat, and proposed a thermometer of a much simpler and more elegant construction. Having adopted linseed oil as a fixed and uniform substance, capable of great dilatation, he discovered by experiment, that distinguishing the capacity of the bulb into ten thousand equal parts, the liquid expanded 256 parts, from melting snow to blood heat, and 725 parts to that of boiling water. These numbers, however, being inconveniently large, he reduced them somewhat more than twenty times, adopting 12 and 34 as the proportional divisions on his scale. But oil, being so viscid a substance, was found to trail and collect on the inside of the tube; and this

thermometer, though constructed on a right principle, never came into general use.

oemer.

Röemer, the Danish astronomer who made the fine discovery of the progressive motion of light, was the first who proposed mercury as the fittest fluid for thermometers; and Halley and Amontons remarked about the same time, that it expands uniformly with heat, and remains nearly stationary at the point of boiling water. On this principle, Delisle, of St Petersburgh, constructed, in 1733, a mercurial thermometer, with a descending scale, the distance from freezing to boiling water occupying 153, or, in round numbers, 150 divisions, of which the bulb itself contains 10,000.

elisle's hermometer.

A more ingenious method, but perhaps too refined, for graduating thermometers, was proposed by Renaldini in 1694. It consisted in adopting the scale in the successive temperatures produced by mixtures in the different proportions of twelve parts of water at the moment of thawing and of ebullition. This suggestion led to a very important inference, since it proved that mercury expands uniformly with equal additions of heat, while alcohol swells constantly in a rising progression.

enaldini.

But the capital improvement of the thermometer was effected by the skill and perseverance of Fahrenheit, whose name has remained justly attached to the instrument. This ingenious person, originally a merchant at Dantzic, who had the misfortune to fail in business, was induced, by his taste for mechanics and chemistry, to have recourse to the manufacture of thermometers, as the means of gaining a slender livelihood. But not meeting with sufficient encouragement at home, he removed, about the year 1720, to Holland, the great emporium of the arts, and fixed his future residence at Amsterdam. He now preferred mercury to alcohol for filling his thermometers; and, adopting the division of the bulb into 10,000 parts, he reckoned 64 of them as the expansion between freezing to blood-heat, and 32 as the contraction from the same point to what he considered as extreme cold, or that produced by the mixture of salt with snow. These numbers were extremely convenient, being found by a repeated bisection. With respect to the heat of boiling water, Fahrenheit discovered the important fact, that it varies with the state of atmospheric pressure. Taking the mean, however, he reckoned 180 degrees from freezing to ebullition, and, therefore, marked this point at 212 on his scale.

ahrenheit's Thermometer.

The thermometer owes its improvement to Celsius, professor at Upsal, who in 1742 placed the commencement of the scale at congelation, and divided the interval thence to boiling water into an hundred degrees, extending such a portion downwards as might be wanted. This centesimal thermometer is exactly the same as what the French have since called the *centigrade*, which, from its fitness and simplicity, deserves to be universally adopted.

The Celsian r Centigrade Thermometer.

The thermometer having been thus carried by successive steps to perfection, it was found by delicate experiments, that, between the points of boiling and freezing, the expansion of mercury amounts to the fifty-fourth part of its bulk, or that it acquires, for each degree of heat, an increase of volume amounting to the 5412th part on the centesimal scale, or the 9742d part on the scale of Fahrenheit. A correction, therefore, on the height of the mercurial column in the barometer, becomes necessary according to the changes of temperature which it undergoes. In this climate, the extreme variation arising from that cause will seldom exceed two-tenths of an inch. But if the barometer be suspended in a room, kept at an agreeable temperature, the error occasioned by the expansion of the mercury may, in ordinary cases, be disregarded, since it will scarcely amount to the twentieth part of an inch.

orrection f the Barometer as ffected by eat.

Since the barometer marks the condition of the distant atmosphere, and intimates those internal alterations which are generally connected with the change of the weather, it is particularly valuable at sea, by forewarning the mariner of the approach of a storm. But an instrument of the ordinary construction would not answer this purpose, the agitation of a vessel on a tempestuous ocean being such as will not only throw the ponderous mercurial column into violent oscillation, but communicate those sudden shocks which must infallibly break the tube. Various attempts have accordingly been made to obtain a *Marine Barometer*, exempt from risk, and yet sufficiently sensible to the variations of the atmosphere. The conical or pendant barometer being, from the narrowness of its bore, rather sluggish, was first recommended for that purpose, though never adopted into practice. About the beginning of the eighteenth century, Dr Hook and Amontons severally proposed to employ for a barometer on board ship, the manometer or air-thermometer. To obviate the derangement arising from the influence of heat, there was to be placed beside it a spirit-of-wine-thermometer, with a ball so large as to give expansions equal to those of the portion of air confined within the bulb. The difference between the two adjacent columns of liquid would therefore measure the variation of external pressure. But to procure such a nice adaptation would prove so extremely difficult in practice, that most probably this instrument was seldom or ever actually constructed. Besides, the liquid column of the manometer, though light and narrow, would yet be much shaken by the rolling and pitching at sea. Notwithstanding these weighty objections, however, this compound manometer was tried in England, mercury being employed as the fluid both of expansion and pressure, and various adjustments applied by means of a complex machinery.

Marine Barometer.

An ingenious and very substantial kind of marine barometer was above twenty years since recommended by Blondeau, one of the professors of the naval academy at Brest. (*See fig.* 11. Plate XXXII.) It consisted of an iron tube, bent below into a syphon, and filled carefully with mercury, which carried a float. For this purpose, a musket-barrel, about three feet long, was chosen, having a very smooth and even bore, and an iron breech closely welded to it, instead of being soldered with brass, which might become corroded by the action of the mercury. The lower end of the tube had a collar of leather, to which was screwed a piece

Blondeau's Marine Barometer.

Barometer. of iron, perforated through its whole length, and bent into an arch, having screwed likewise, with a collar of leather at its other extremity, a vertical cylinder of iron, four inches high, and of the same bore exactly as the tube. The contracted aperture at the end of the tube, not being exactly in the middle, was not always opposite that of the arch; and, therefore, by turning it occasionally aside, the communication could be contracted at pleasure, or even obstructed entirely. The cylindrical appendix was tapered at the top to a narrow orifice, through which an iron wire, attached to a small ivory float, had been introduced. To prepare this instrument for action, the mercury was first boiled in the tube; then the arch, filled with hot mercury, was screwed to the end, the cock opened, and the surplus mercury allowed to flow over; next the vertical piece, with its float, was screwed on, and a little mercury added, to give it due play. The origin of the scale was to be determined from the comparison with another good barometer of the ordinary construction; but, owing to the equality of the bores of the opposite tubes, the divisions were only half the usual size, or the inches were exhibited by half-inches.

This species of barometer is certainly free from all sort of risk, while the facility which, by means of turning the arch, it affords in checking the ascent and descent of the mercury, prevents in a great measure the oscillations of that fluid. If the instrument were properly suspended, therefore, its indications would be tolerably steady and regular. The chief objection to it consists in the diminutive range of its scale.

In every marine barometer, the main object is to give steadiness to the mercurial column, by retarding its motion in the tube; in short, to imitate the equalizing effect of the fly in mechanics. One form of construction was, instead of the cistern below, to annex a spiral tube composed of a number of horizontal convolutions. Passement, an ingenious Parisian artist, about the year 1758, improved on this idea. He twisted the barometer tube near the middle, at least twice round, and joined to its upper end a wide cylinder. But more effectually to prevent all irregular oscillations, he took a tube with a very narrow or capillary bore, and contracted it below, while he annexed a wide cylindrical piece at its other extremity. The only thing wanted now to the perfection of this instrument, was to devise a mode of suspending it that should soften the jerks, and allow it generally to maintain a vertical position. Our English artists have, by repeated trials, at last succeeded in surmounting all the difficulties. The marine barometer, manufactured by Mr Cary of London, (*See fig.* 12, Plate XXXII.) is one of the most approved kind. It consists of a capillary tube, about twenty-seven inches long, with a bore scarcely exceeding the thirtieth part of an inch, but terminated by a cylinder four or five inches high, and nearly three-tenths of an inch in diameter. It is suspended by a spring and jimbols, near the top at a certain point, which in each case is discovered by actual trial. By making the suspension lower, it is found, that the agitation of the barometer will cause the mercury to rise a little; while, by placing the suspension higher, the mercurial column suffers always some depression. The reason of this curious observation is not well explained. It probably results from the different centrifugal tendencies communicated to the opposite portions of the columns. The swinging of the instrument would evidently augment the pressure of the upper portion of the column, while it diminished that of the under portion. But this lower portion, being longer than the other, its tendency to descend would be proportionally so much greater. About the point of suspension, however, the opposite effects of the centrifugal tendencies are balanced, since the superior force being employed to set in motion a narrower column, the reflux and efflux of the mercury in the upper cylinder must be preserved nearly equal.

Barometer.

Marine barometers, thus improved, are now very generally used, and with great benefit to the public service, on board ships of war and Indiamen. To facilitate the keeping of a register of barometrical observations, the meritorious and indefatigable Mr Horsburgh, hydrographer to the East India Company, has lately published a set of engraved ruled sheets, adapted for the convenience of navigators. In these plates, the height of the mercury, from twenty-seven to thirty-one inches, is represented, in inches and tenth parts, by horizontal lines, while each successive day has a space apportioned to it by vertical bars. The state of the barometer at every observation is marked with a dot, and these dots being afterwards connected together, exhibit an irregular waved line, stretching across the sheet, and indicating the series of the changes of the weather. At the lowest points, from which the curve again returns, a gale generally follows. From the observations made off the Cape of Good Hope, during the month of May 1815, by an ingenious and active young officer, Captain Basil Hall, of his Majesty's sloop Victor, it appears that whenever the mercury fell to 29,60 inches, a storm ensued; the column always rose when the gale abated, and when it reached near thirty inches, the weather became fair. Those gales often came on suddenly, without any visible change in the aspect of the sky, but the marine barometer never failed to give warning of their approach.

Horsburgh's Plates.

To explain the cause of the variations of the barometer, has long perplexed philosophers. Many hypotheses have at different times been advanced on the subject; but it would be a mere waste of time, to make any detailed recital of such crude and unsatisfactory attempts. The various and often imaginary effects of vapours of heat and winds have been employed in framing an explication of the changes of the atmosphere. The fact that the mercurial column generally falls before rain, seemed at complete variance with the intimation of the senses, it being a notion universally prevalent, that the air is heavier when the sky appears lowering and overcast; another proof, if it were wanted, how fallacious are all current opinions in matters of science.

Difficulty in explaining the variations of the Barometer.

Leibnitz, fancying he had discovered a new principle in hydrostatics, endeavoured, by a sort of metaphysical argument, to demonstrate that, though a body

Barometer. adds its own weight to the pressure of a fluid in which it is suspended, yet it will cease to be ponderous in the act of falling. This alleged principle will not, in the actual state of science, be thought to require any serious refutation; nor, were it even admitted, would it be found at all adequate to the explication of the phenomenon, since the weight of moisture precipitated from the whole body of atmosphere could never, by the absence of its pressure, occasion a diminution of the tenth part of an inch in the altitude of the mercurial column.

Dr Halley and Mairan sought to account for the depression of the barometer before a storm, to the withdrawing of the vertical pressure of the atmosphere, when borne swiftly along the surface of the globe by a horizontal motion. This hypothesis at first sight appears very plausible, and might seem farther confirmed by a noted experiment which most authors have admitted without due examination.

Hauksbee's Experiment.

Hauksbee, a skilful and ingenious experimental philosopher, about the year 1704, placed two barometers, about three feet asunder, with their naked cisterns in two close square wooden boxes, connected by a horizontal brass pipe; one of these boxes had, inserted at right angles, an open pipe on the one side, and a second pipe terminating in a screw, on the other side; to this end he adapted a strong globular receiver of about a foot in diameter, which had been charged, by injection from a syringe, with three or four atmospheres; then suddenly opening the stop-cock, and giving vent for the escape of the air through the box and over the surface of the included cistern, the mercury sunk equally in both the barometers more than two inches.

This elegant experiment might be deemed entirely conclusive, if a minute circumstance, on which the success really depends, had not unfortunately been overlooked.

Its Fallacy.

It will be perceived from the inspection of the figure which Hauksbee has given, that the exit pipe of the box was considerably wider than the pipe which conveyed into it the stream of air. This fluid, escaping from compression, would, therefore, be carried by its elasticity as much beyond the state of equilibrium; while the width of the orifice, by facilitating its emission, would allow the portion occupying the box and the connected reservoir to preserve its acquired expansion. If the pipe of discharge from the box had been much narrower than the other, an opposite effect must have taken place; for the air accumulated over the cistern, not finding a ready vent, would remain in a state of condensation. This curious fact is another of the many instances which might be cited to show the great delicacy and circumspection required in performing philosophical experiments.

The same results, however, can be exhibited by a very simple apparatus. Let a small box, or rather a glass ball, have a short narrow tube inserted in the one side, and another wide tube opposite to this, with a cross-slider of brass, for contracting the orifice at pleasure; and, to the under part of the ball, join a long perpendicular tube, bent back like a syphon to more than half its height and containing a double column of water. Now, blow through the narrow tube into the cavity of the ball, while the orifice of emission is quite opened, and the liquid will rise several inches in the long stem; but, still continuing the blast, let the orifice be gradually contracted, and the column will first descend to its ordinary level, and then sink considerably below it.

Causes of the Variation of the Barometer.

The fall and rise of the mercury in the barometer must evidently be occasioned by some corresponding reduction or accumulation of the atmosphere at the place of observation. Whatever augments the elasticity of the air will cause part of the incumbent fluid to evade and leave for the time a diminished vertical pressure. The efflux of wind might also produce a temporary reduction of the atmospheric column. But the real difficulty consists in explaining why the variations of the barometer should be greater in the high latitudes than between the tropics, and why they so much exceed in all cases the quantities which calculation might assign.

The influence of heat will account for the semidiurnal variations of the barometer which are observed, especially within the torrid regions. From ten o'clock in the morning till four in the afternoon, the mercury generally falls; but, after that hour, it rises again, till ten o'clock at night, when it drops till four in the morning, and then mounts till ten o'clock in the forenoon. These regular changes, which amount to about the five-hundredth part of the whole atmospheric pressure, depend on the prevalence of the alternating land and sea breezes, occasioned by the diversified action of the sun's rays upon the earth and water. The accumulation of air is greatest at four o'clock in the morning and evening, and the mercury then attains its highest point; but it sinks lowest at ten o'clock in the morning and evening, when the incumbent mass has been the most reduced.

A similar reason will explain the effects of the northerly and easterly winds, in elevating the mercury of the barometer in our climate. A chill air, with enfeebled elasticity, is thus accumulated, and exerts a predominant pressure.

The augmented elasticity communicated to the air by the action of heat or the presence of humidity, and the reduction of the incumbent mass by the efflux of winds, have each their distinct influence, in disturbing the equilibrium of atmospheric ocean. But the effects, particularly in the high latitudes, much surpass the regular operation of those causes. The only mode, perhaps, of removing the difficulty, is to take into consideration the comparative slowness with which any force is propagated through the vast body of atmosphere. An inequality may continue to accumulate in one spot, before the counterbalancing influence of the distant portions of the aërial fluid can arrive to modify the result. In the higher latitudes, the narrow circle of air may be considered as, in some measure, insulated from the expanded ocean of atmosphere, and hence, perhaps, the variations of the barometer are concentrated there, and swelled beyond the due proportion. We content ourselves with throwing out this hint at present, but hope to be able to resume and discuss the subject at some length under the article CLIMATE. (D.)

BAROMETRICAL MEASUREMENTS.

Barometrical Measurements.

It was remarked in the preceding article, that the decisive experiment by which Pascal established the reality of atmospheric pressure, had likewise suggested to this ingenious philosopher the method of determining the elevations of distant points on the surface of the globe. But the first attempts were very rude, proceeding on the inaccurate supposition that the lower mass of air is a fluid of uniform density. Different authors estimated variously from eighty to ninety feet as the altitude, which corresponds to a variation of the tenth part of an inch in the mercurial column. The Torricellian tube or cane, as it was then called, was, on its first introduction to England, carried accordingly to the tops of mountains, or conveyed to the bottom of pits and mines, or even let down to great depths in the sea.

Sinclair.

Among those experimentalists who laboured most assiduously in the study and application of the barometer in this part of the island, we should mention George Sinclair. This ingenious person had been Professor of Philosophy in the University of Glasgow, but seems to have conscientiously resigned his office soon after the Restoration, rather than comply with that hated episcopacy which the minions of Charles II. had forced upon the people of Scotland. He then retired to the village of Tranent, not far from Edinburgh, and was employed as a practical engineer, in tracing the levels of coal-pits, in directing the machinery employed in the mines at Leadhills, and afterwards in the great undertaking of conducting water from the heights of the Pentlands to supply the northern metropolis. Though not a profound mathematician, he was skilled in mechanics and hydrostatics, and possessed no small share of invention. Sinclair is said to be the first who applied to the mercurial tube the name of *baroscope*, or *indicator of weight*, the more definite appellation of *barometer*, or *measurer of weight*, not having been appropriated till many years afterwards. During his excursions in 1668 and 1670, he employed that instrument to measure the heights of Arthur's Seat, Leadhills, and Tinto, above the adjacent plains. He followed the original mode of using a tube sealed at the top, with a paper scale pasted against the side, which he carried to the top of the mountain, where he filled it with mercury; and, inverting it in a bason, he noted the altitude of the suspended column, and repeated the same experiment below; a very rude method certainly,—but no better was practised in England during the succeeding thirty years.

Barometrical Measurements.

In a small scarce tract, printed in 1688, and bearing the quaint title of *Proteus bound with Chains*, Sinclair gives some judicious remarks on the variations of the barometer, considered as a weather-glass, and delivers very sound opinions, on the whole, respecting the causes of the chief meteorological phenomena. In a postscript to that piece, he proposes a most efficient and ingenious method of weighing up wrecks from the bottom of the sea. It consisted in employing two large arks, or square wooden boxes, fastened to the sides of the ship, and charged with air carried down to them by a succession of inverted casks, open at the lower end. An ark of a cubical shape, and twenty feet in every dimension, the smallest which he mentions, would, as he computes, have a buoyancy equivalent to 448,000 pounds Troy. It is remarkable that the celebrated Mr Watt always employs this very mode, using a large gazometer, floating in a pond dug in the court of his manufactory, and charged gradually by the action of bellows, for raising the ponderous engines constructed at Soho, and lifting them over his walls into the boats, which are stationed to receive them in the adjacent canal.*

Relation of the Air's Density and Elasticity.

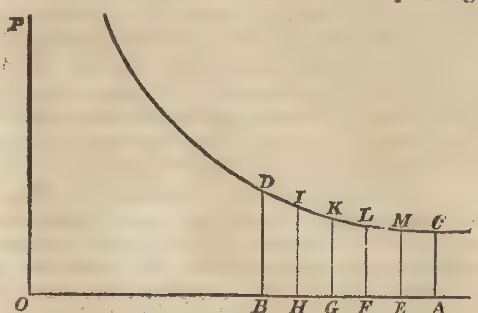
In all the computations hitherto made from different altitudes of the barometer, the air was considered as an uniform fluid; no regard being had to the gradual diminution of density which must evidently take place in ascending the atmosphere. To estimate the effect of that gradation, it became requisite previously to determine the actual relation subsisting between the density of the fluid and its elasticity. This was first ascertained in England by Townley, who inferred from some experiments of Boyle, that the elastic force which the air exerts is exactly propor-

* Sinclair was author of a well-known little book, entitled, *Satan's Invisible World Discovered*, which, at a former period, was sold at all the public fairs in the country, and devoured with eagerness and dismay by the Scottish peasantry. In a quarto volume, on *Hydrostatics, and the Working of Coal-mines*, printed in Holland, and published by subscription in 1672, he digressed so widely from his subject, as to insert *A True Relation of the Witches of Glenluce.* But this was the folly of the age, which several of the most learned men had not been able to escape. It is painful to observe, that James Gregory, the inventor of the reflecting telescope, who, although endowed with talents of the highest order, yet appears to have had a keen temper, and to have imbibed an hereditary attachment to royalism and episcopacy, should have stooped to attack an unoffending and less fortunate rival. He wrote a little tract against Sinclair's Hydrostatics, with the title of the *Art of Weighing Vanity*, and under the thin disguise of Patrick Mather, archbeadle to the University of St Andrew's. It is a piece full of low scurrility, and memorable only for a very short Latin paper appended to it, containing the series first given to represent the motion of a pendulum in a circular arc. In the British Museum, there is a letter of Gregory to Collins, the secretary of the Royal Society, boasting of his project, and soliciting information, with which to overwhelm the poor author. But with all his eagerness to hunt down Sinclair, he never touches on the strange episode of the witches of Glenluce. What a picture of times approaching so near our own!

tional to its density. A similar conclusion was about the same time drawn by Mariotte, a French philosopher, from a still better series of experiments. Following out this very simple law, he thought of computing heights from barometrical observations, by the rules usually employed in constructing tables of logarithms; and had, therefore, obtained some glimpse, no doubt by a sort of conjectural process, of the remarkable result, that the density of the atmosphere decreases in a geometrical progression, corresponding to the elevations taken after an arithmetical one. But seemingly not aware of the importance of the principle at which he was pointing, Mariotte immediately deserted it; and calculating from a repeated bisection of the column of air between the two stations into successive horizontal strata, he contented himself with interpolating the densities according to a harmonic division, which he next abandoned for the simplicity of a series with equal differences. This able experimenter hence only sketched out a mode of investigating the problem of barometrical measurements, without arriving at any very definite or consistent rule of solution.

elation of mosphe- Density d Eleva- n.

In 1686, the ingenious and active philosopher Dr Halley resumed the subject, and discovered the law that connects the elevation of the atmosphere with its density; of which he gave a clear demonstration, derived from the well known properties of the hyperbola referred to its asymptotes. Since the height of the mercury indicates the pressure, and consequently the elasticity of the external air, it must be proportioned likewise to the density. Wherefore the breadth of a given mass of air, or the thickness of a stratum which corresponds to a certain portion of the mercurial column, will be inversely as this altitude. Let O be the centre of a rectangular hyperbola, of which OA and OB are the asymptotes; and conceive the distances OA and OB to represent the heights of the mercury at two stations. The perpendiculars AC and BD, which are reciprocally as OA and OB, must hence express the relative thickness of strata corresponding to



equal portions of the barometric scale. Divide AB into a multitude of equal segments, and erect the perpendiculars EM, FL, GK, and HI. The intercluded spaces, from AC to BD, will denote the successive thickness of the series of strata into which the whole mass of air between the two stations is subdivided. Consequently the aggregate or mixtilineal space DBAC, which is proportional to the logarithm of the ratio of OB to OA, will express the difference of atmospheric elevation when the mercurial column mounts from B to A. Taking equal ascents, therefore, in the atmosphere, the corresponding densities must form a decreasing geometrical series.

Rule Deduced.

To apply this elegant theorem, Dr Halley availed himself of the best experiments which had been performed to determine the relative densities of air, water, and mercury. In different trials made near the earth's surface, it was found, when the barometer stood at $29\frac{3}{4}$ inches, that the air is 840, 852, or even 860 times lighter than water. Taking round numbers, therefore, and assuming the specific gravity of mercury to be $13\frac{1}{2}$, he reckoned $800 \times 13\frac{1}{2} \times 30 = 10{,}800$ inches, or 90 feet, as the altitude of an atmospheric column which, near the surface, would exert a pressure equivalent to that of an inch of mercury. For the coefficient, which answers to the actual constitution of the atmosphere, Halley should have taken the thirtieth part of .4342945, the modulus of the common system of logarithms, or .0144748. But he proceeded less directly, having satisfied himself with taking the arithmetical mean between the differences of the logarithms of 29 and 30, and of those of 30 and 31; a compensation of errors, which gives .0144765, hardly deviating from the former. Hence he gave this simple analogy for computing the heights of mountains by the barometer; *as the constant number .0144765 is to the difference between the logarithms of the barometric columns at the two stations, so is 900 feet to the elevation required.* The result of this operation is evidently the same as if the logarithmic difference had been multiplied by the number 62170; a very tolerable approximation at all seasons for a northern climate, and quite accurate, indeed, if the mass of intervening air had a medium temperature of 46° by Fahrenheit's scale. Dr Halley supposed that the observations themselves might, from the influence of heat, differ about the fifteenth part between summer and winter. But the thermometer was still so imperfect an instrument, that it could not be applied with confidence in correcting such variations.

Otherwise Investigated.

The principle which Halley thus investigated might be derived from a simpler process. Conceive the atmosphere to be divided into a multitude of equally thin horizontal strata, it is obvious that each successive stratum would, to the pressure of the superincumbent stratum, add its own weight, which being as its density or elasticity, is therefore proportioned to the collective pressure; and, consequently, those densities will continually increase in going downwards, exactly in the same way, and after a like progression, as money accumulates at compound interest, where a constant portion of the aggregate fluid is regularly joined to the capital. Such, in fact, is the distinguishing character of a geometrical progression, that the increase or decrease of each succeeding term is always proportioned to the term itself. The logarithmic curve is hence the best adapted for exhibiting the relations which connect the densities with the elevations in the atmosphere; the axis of the curve expressing the elevation, while each ordinate represents the corresponding density of the stratum of air. It being a fundamental property of the logarithmic curve, that every subtangent applied to it has the same length, the exact determination of this in the case of our atmosphere, is

the only thing wanted for the final solution of the general problem.

Eleven years after Dr Halley had given his rule for barometrical measurements, this philosopher had an opportunity of applying it to discover the height of Snowdon in North Wales. He found that the barometer which stood at 29.9 inches on the sea-shore near Caernarvon, fell a few hours after, when planted on the summit of the mountain, to 26.1 inches, the altitude having been ascertained previously by a trigonometrical observation to be 1240 yards.

Newton's General Solution.

The year 1687 is memorable as the date of the first publication of the *Principia*, which was drawn up chiefly at the urgent request of Halley, from disjointed materials that had lain a considerable time in the author's hands. In that immortal work, Newton resumed the problem of the gradation of atmospheric density, and solved it in that general way which suited his penetrating genius. He demonstrated that, supposing the particles of air, like other bodies, to have their weight or gravitating tendency diminished as the squares of their distances from the centre of the earth, if those distances be taken in harmonic progression, the corresponding densities of the atmosphere will form a geometrical one. But since the diminution of attraction at the greatest height we are able to reach, amounts only to the two thousandth part of the whole; this difference is too minute to be admitted into practice; and the simpler law first established by the sagacity of Halley may be deemed sufficiently accurate for every real purpose.

Newton has given a sort of geometrical solution of the problem. But a more precise, and, in this case, a clearer investigation, is obtained by help of the symbols of the integral calculus. Let x and x' express the altitudes of two strata of atmosphere, and y and y' the corresponding densities, the radius of the earth; suppose farther, that e represents the altitude of the equiponderant column which measures the elasticity of the air. Since the density of the air depends on the incumbent pressure, its decrement must evidently be proportional to the weight of each superadded minute stratum, or to the density of this stratum multiplied into its thickness and power of gravitation. Whence $-edy = ydx\left(\frac{r}{r+x}\right)^2$, or $-\frac{edy}{y}=\frac{r^2dx}{(r+x)^2}$, of which the complete integral is e H Log. $\frac{y'}{y}=\frac{r^2}{r+x}-\frac{r^2}{r+x'}, = \frac{r^2}{r+x}\cdot\frac{x'-x}{r+x'}$. If r be regarded as indefinitely great in comparison of x, the expression will pass into e H Log. $\frac{y'}{y} = x'-x$, which is only the common formula.

Application of the Thermometer.

Little seemed wanting, therefore, to complete the practice of barometrical measurements, but the application of the thermometer, to correct the results. This instrument, however, advanced slowly to perfection, and more than forty years yet elapsed before it came into current use. Some of the continental philosophers likewise, biassed, perhaps, by a secret jealousy of the superiority which England had acquired in science, began to throw out doubts respecting the reality or accuracy of the law of geometrical progression in the atmosphere. Daniel Bernoulli, a man of candour on the whole as well as ingenuity, but who, with some proneness to speculative reasoning, had imbibed unfortunately many of the prejudices of the Cartesian and Leibnitzian schools, proposed in his capital work, the *Hydrodynamica*, which came out in 1736, certain vague hypotheses regarding the constitution of the atmosphere, as deduced from certain internal motions attributed to its component strata. The specious results of those calculations led him hastily to deviate from the principle of the geometrical progression of density in the upper regions. In this departure he was followed by Cassini and Horrebow, who concluded from some partial observations they had made, that the barometer, in its indications of atmospheric pressure, is subject to irregularity; and that, near the surface of the earth, it obeys a different law from what it obtains at great elevations. A strong light, however, was thrown upon the subject in 1753 by Bouguer, an able mathematician, and a very skilful and ingenious observer, who, with other academicians, had been employed for several years in measuring a degree of the meridian along the stupendous ridge of the Andes. From the comparison of more than thirty distinct observations, he deduced a simple and elegant rule for computing heights by means of the barometer. It is, that the difference between the logarithms of the mercurial columns at the two stations being diminished by one-thirtieth part, and the decimal point shifted four places to the right, will express the required elevation in *toises*. Since the English was to the French foot nearly as fifteen to sixteen, the rule would be accommodated to our measures, and the result expressed in feet, if the logarithmic difference were augmented by the thirtieth part, then multiplied by six, and the decimal point thrown back four places; or, what is the same thing, if that logarithmic difference were multiplied at once by 62,000. But Bouguer imagined, that this rule would not hold exactly in Europe, or in the lower regions of the torrid zone; and to explain the deviation, he had recourse to the forced supposition that the particles of air possess different degrees of elasticity. Lambert, a philosopher of great originality and penetration, afterwards published some excellent remarks on the comparison of barometrical measurements. But no material progress was made till 1755, when M. de Luc of Geneva resumed the subject, and carefully combined experiment with observation. For the space of upwards of fifteen years, he prosecuted his inquiries with diligence and perseverance, aided by the peculiar advantages of local situation, in a city abounding with skilful artists, and seated in the neighbourhood of lofty mountains. The discrepancies which had hitherto created so much embarrassment, proceeded mostly from the inattention of observers to the disturbing influence of heat, and particularly its effect in expanding the air, and consequently augmenting the elevation due to a given difference of atmospheric pressure. De Luc's first object was to improve the thermometer of Reaumur, which, though greatly inferior to that of Fahrenheit, had been adopted in France and the adjacent parts of the continent. Having ascertained that mercury has

Bouguer.

De Luc.

Barometrical Measurements.

the valuable property of expanding equably with equal additions of heat, he substituted that metallic fluid for spirit of wine, but retained its arbitrary and inconvenient scale of 80 degrees between the points freezing and boiling water. He next examined the dilatation of air at different temperatures, and corrected those results by numerous observations made on the mountains of Savoy, and the mines of the Hartz, in which the barometer was combined with the thermometer. The *formula* which he thence deduced for the computation of barometrical measurements was, in 1772, published in his *Recherches sur les Modifications de l'Atmosphere*, and seemed to draw, especially in England, a very considerable degree of notice. Dr Maskelyne, the astronomer-royal, adapted it to our system of measures, and Dr Horsley made annotations and comments on it. But, what was of more importance, other accurate observers, incited by De Luc's example, entered the same field of inquiry, provided with instruments of greater delicacy and much better construction. In 1775, Sir George Shuckburgh Evelyn visited the Alps, and combined trigonometrical operations with corresponding observations by barometers and thermometers from the hands of Ramsden; and about this time likewise, General Roy not only measured, with instruments made by that excellent artist, some of the principal mountains in Scotland and Wales, but instituted a series of manemetrical experiments. It resulted from all these researches that, for each degree on Fahrenheit's scale, mercury expands the 9700th part, and air the 435th part of their respective bulks. It further appeared that the atmosphere has its temperature almost uniformly diminished at equal ascents; and that the logarithmic difference, reckoning as integers the first four digits, expresses in English fathoms the height of an aërial column as cold as the point of congelation. General Roy proposed likewise another correction depending on the enfeebled gravity, and consequently the augmented altitude of the equiponderant column of atmosphere in the lower latitudes, occasioned by the influence of centrifugal force arising from the earth's rotation. Several years afterwards, Professor Playfair, in a learned paper, printed in the first volume of the *Transactions of the Royal Society of Edinburgh*, examined all the circumstances which can affect barometrical measurements, and discussed each question with the correctness and perspicuity that we might expect from his distinguished abilities. At nearly an equal interval of time, the celebrated Laplace resumed the subject in his *Mecanique Celeste*, and brought all the conditions together in a very complicated formula. Such an appearance of extreme accuracy, however, is perhaps to be regarded merely as a theoretical illusion, unsuited and inapplicable to any real state of practice. Biot has since attempted to arrive at a similar conclusion, by setting out *à priori* from some careful experiments on the relative density of air and mercury, performed by him in conjunction with Arago. He thence infers, that, in the latitude of Paris, and at the point of congelation, air, under a mercurial pressure of 76 *metres*, or 29.922 English inches, is 10,463 times lighter than mercury at the temperature of water at its lowest contraction. This would give 26,090 feet for the height of a column of homogeneous fluid, whose pressure is equivalent to the elasticity of the atmosphere. The coefficient adapted to common logarithms, and adjusted to the force of attraction at the level of the sea, would therefore be 60,148 feet, or 18,334 *metres*; scarcely differing sensibly from the quantity which Ramond had deduced from a very numerous set of experiments made by him on the Pyrenees. But Biot prefers, as the coefficient, the number 18,393, answering for an elevation of 1200 metres, or about 4000 feet above the sea, which is not far from the general level of such observations. The formula is hence, in English feet, $60{,}346\,(1+.002837 \cos. 2\psi)\left(1+\frac{2(T+t)}{1000}\right)\log.\frac{H}{h}$; where ψ denotes the latitude of the place, T and t the temperatures of the air at the two stations, as indicated by the centesimal thermometer, and H and h the heights of mercurial columns corrected for the effects of heat.

Shuckburgh, and Roy.

Formula of Laplace.

This active writer has likewise given tables for expediting the calculation of barometrical measurements; in which he was anticipated, however, by Oltmans of Berlin, who published, in 1809, large *Hypsometrical Tables*, as they are called, accommodated to the complex formula of Laplace. Such tables might, no doubt, prove useful where very frequent computations are wanted, as in the case of the reduction of the numerous observations brought home by Baron Humboldt, for which, indeed, they were first designed. But still they contain a needless profusion of figures, and hold forth a show of extreme accuracy which the nature of the observations themselves can never justify. The mere calculation of barometrical measurements is a secondary object; the great difficulty is to procure good observations, and to combine tolerable accuracy with expedition. For this purpose, a very portable barometer is still wanted;—an instrument light and commodious, exempt from injury or derangement, and yet sensible to minute changes of atmospheric pressure. These properties, indeed, are seldom conjoined, and one advantage must generally be sacrificed to obtain another.

Mountain Barometer.

A barometer of the most improved construction is represented in fig. 19; a portion of the tube is shown in fig. 20; and a section of its cistern in fig. 21. By help of a screw pressing against the bottom of a leather bag, inclosed within a cylindrical ivory box, the mercury is always brought up through a tubular aperture to the same precise level; or till its convex surface appears to touch a very thin line of light, which is admitted through a slip of ivory applied against the side of the chink or separation of this tube from a wider one immediately over it. The lower end of the mercurial column being thus adjusted, the length is easily measured by drawing gradually down a hollow brass tube, divided at intervals by wide slits, covered on one side by thin bits of ivory, till by that softened light a contact is observed with the edge of a slit and the convex top of the column. The fine Vernier which the moveable tube carries gives the altitude of the mercury in thousandth parts of an inch. A thermometer is likewise constantly attached to the instrument, for the purpose of indicating the temperature of the mercury, which, from the heat of the hand in carrying,

Barometrical Measurements.

or the influence of the solar beams, is commonly warmer than the external air.

This mountain barometer is suspended for observation by jimbols from a tripod, as exhibited in fig. 18; but its several parts can be folded up together into a convenient compass, tolerably well fitted for carriage, as represented in fig. 19. The whole apparatus may not exceed the weight of ten pounds, yet even this, moderate as it might seem, would be felt a serious encumbrance by a traveller who is engaged, day after day, in the labour of climbing mountains. The risk which the instrument incurs, besides, in transporting it perhaps over rough precipices, imposes a perpetual constraint, while, to make correct observations with it, must always require time and patient attention. A lighter and more compact, though less accurate, barometer will generally be preferred by the geological traveller, whose object is rather to extend our acquaintance with the altitudes of mountains, than to aim at a superfluous and often illusory precision. The portable instrument, invented by Sir Henry Englefield, and represented in fig. 14, will, on the whole, answer those views. Its cistern is formed of box-wood, sufficiently tight to hold the mercury, without preventing the access and impression of the external air. When this barometer is inverted, the mercury, therefore, subsides very slowly in the tube, which must be firmly suspended in a vertical position. For greater security, the mercury is now put into a leathern bag introduced within the cistern.

Portable Barometer of Sir H. Englefield;

and of Gay-Lussac.

A very simple and convenient sort of portable barometer was lately invented in France by that celebrated chemical philosopher M. Gay-Lussac. (*See* fig. 15 and 16.) It consists of rather a wide syphon tube, filled with mercury, and sealed hermetically at the inverted end, having a very fine capillary hole formed about an inch under this, by nicely directing the flame of a blow-pipe against the side of the glass, and drawing a melted spot of it out to a point. The lower portion of the principal branch has its bore contracted to less than the tenth part of an inch, to prevent the mercurial column from dividing in the act of inverting it. The mercury is boiled as usual, and the tube may be concealed in a walking stick, or lodged, like the complete mountain barometer, in a cylinder of brass, with moveable sliders bearing the divisions of a Vernier at both ends. (*See* fig. 17.) For greater simplicity, however, the larger divisions might be engraved on the tube itself. This kind of barometer is of ready use, and very little exposed to hazard in carriage. It is commonly held in a reclined or inverted position; but, in making an observation, it must be gently turned back, and kept perpendicular till the mercury descends through the contracted bore, and slowly rises again in the opposite short branch; the scale is noticed at both ends of the incurved column, and the difference of those indications gives its correct altitude.

Modified Conical Barometer.

A modification of the conical barometer, which, in travelling, we have ourselves employed with great ease and advantage, should likewise be mentioned. The principal part of it consists of a small stop-cock made of steel, and represented in fig. 13. A glass tube of 31 or 32 inches long, with a bore of the tenth part of an inch hermetically sealed at the top, and filled with quicksilver, is cemented into the one end of the stop-cock; and into the other end is cemented an open and wider tube, 16 inches or more in length, and having its diameter above the eighth part of an inch. This compound tube is lodged in a walking-stick, divided into inches and tenths through its whole extent, or only at the upper part, if uniform tubes be selected. In making an observation, the cock is turned, and the instrument inverted. The upper column then descends partly into the lower tube, till it becomes shortened to the proper altitude.

Barometrical Measurements.

We have already stated the principles on which the calculation of barometrical measurements proceeds. But there still are some points, either assumed or overlooked, which may considerably modify the results. It is presumed, that, at equal successive heights, the temperature of the atmosphere decreases uniformly. This property, however, does not hold strictly, and it may be shown from a comparison of the best observations, that the decrements of heat follow a quicker progression in the higher regions. But we shall soon have another opportunity to examine this subject, and trace out its various consequences.

The humidity of the air also materially affects its elasticity, and the hygrometer should, therefore, be conjoined with the thermometer in correcting barometrical observations. But nothing satisfactory has yet been done with regard to that subject. The ordinary hygrometers, or rather hygroscopes, are mere toys, and their application to science is altogether hypothetical. A most philosophical course has lately been pursued, by multiplying calculations grounded on very loose data, instead of instituting a nice and elaborate train of original experiments.

In the actual state of physical science, it is preposterous, therefore, to affect any high refinement in the formula for computing barometrical measurements. The whole operation may be reduced to a very short and easy process. But the simplicity of the calculation would be still greater, if the centesimal thermometer were generally adopted. It will be sufficiently accurate, till better data are obtained, to assume the expansion of mercury by heat as equal to the 5000th part of its bulk for every centesimal degree, while that of air is twenty times greater, being an expansion for each degree of the 250th part of the bulk of this fluid. 1. *Correct the length of the mercurial column at the upper station, adding to it the product of its multiplication into twice the difference between the degrees on the attached thermometers, the decimal point being shifted four places to the left.* 2. *Subtract the logarithm of this corrected length from that of the lower column, multiply by six, and move the decimal point four places to the right; the result is the approximate elevation expressed in English feet.* 3. *Correct this approximate elevation, by shifting the decimal point three places back to the right, and multiplying by twice the sum of the degrees on the detached thermometers; this product being now added, will give the true elevation.*

Rule for Computing Barometrical Measurements.

If it were judged worth while to make any allowance for the effect of centrifugal force, this will be easily done, before the last multiplication takes place, by adding to twice the degrees on the detached thermometers, the fifth part of the mean temperature corresponding to the latitude. The mean temperature itself is formed by multiplying the square of the cosine of the latitude by 29.

Barometrical Measurements. Examples.

In illustration of these rules, we shall subjoin some real examples. General Roy, in the month of August 1775, observed the barometer on Caernarvon Quay, at 30,091 inches, the attached centesimal thermometer indicating 15.7, and the detached 15.6; while, on the peak of Snowdon, the barometer fell to 26.409 inches, and the attached and detached thermometers marked respectively 10°,0 and 8°,8. Here twice the difference of the attached thermometers is 11°.4, and twice the sum of the detached thermometer is 48°.8, which becomes 50.8, when augmented by the fifth part of the mean temperature on that parallel. Now, omitting the lower decimals, the first correction is .00264 × 11.4 = .030, to be added to 26.409. Wherefore,

$$\begin{aligned} \text{Log. } 30.091 &= 1.4784366 \\ \text{Log. } 26.439 &= 1.4222450 \\ \text{Difference} &= .0561416 \\ \text{Constant multiplier} &= 60000 \\ \text{Approximate height} &= 3368.496 \end{aligned}$$

And, for the true height, the correction is 3.37 × 50.8 = 171.2, which gives 3340 for the final result.

We shall take another example from the observations made by Sir George Shuckburgh Evelyn, at the same period, among the mountains of Savoy. This accurate philosopher found the barometer, placed in a cabin near the base of the Mole, and only 672 feet above the surface of the lake of Geneva, to stand at 28,152 inches, while the attached and detached thermometers indicated 16°.3 and 17°.4; but, another barometer carried to the summit of that lofty insulated mountain, the mercury sunk to 24,176 inches, the attached and detached thermometers marking 14°.4 and 13°.4. Wherefore, twice the difference of the degrees on the attached was 3°.8, and twice the sum of the degrees on the detached thermometer was 61°.6. Consequently, the correction to be applied to the higher column was .0024 × 3.8 = .009, which makes it 4.185. Now,

$$\begin{aligned} \text{Log. } 28,152 &= 1.4495092 \\ \text{Log. } 24,185 &= 1.3835461 \\ \text{Difference} &= .0659631 \\ \text{Constant multiplier} &= 60000 \\ \text{Approximate elevation} &= 3957.786 \end{aligned}$$

To correct this approximate elevation, remove the decimal point three places back, and multiply it by 61°.6, increased by 2°.9, the fifth part of the mean temperature, corresponding to the latitude; but 3.96 × 64.5 = 255.4, and 3957.8 + 255.4 = 4213. Hence the summit of the Mole is 4885 feet above the lake of Geneva, or 6083 feet above the level of the Mediterranean Sea.

The last example we shall give is drawn from the observation which Baron Humboldt made among the Andes, near the summit of Chimboraço, the highest spot ever approached by man. This celebrated traveller found there, that the barometer fell to 14,850 English inches; the attached thermometer in the tent being at 10°, and the detached in open air being 1.6° under zero. But the same barometer, carried down to the shore of the Pacific Ocean, rose exactly to 30 inches, while both the attached and detached thermometers stood at 25°.3. Consequently the correction to be applied to the upper column is = .0015 × 30.6. = .045. Wherefore,

$$\begin{aligned} \text{Log. } 30,000 &= 1.4771213 \\ \text{Log. } 14.895 &= 1.1730405 \\ \text{Difference} &= .3040808 \\ \text{Constant multiplier} &= 60000 \\ \text{Approximate elevation} &= 18244.848 \end{aligned}$$

Now, the difference of the detached thermometers or 26.9° being doubled and farther increased by 5.8°, the fifth part of the mean temperature at the equator, makes 59°.6; the final correction to be applied is therefore = 18.24 × 59°.6 = 1087, which gives 19,332 feet for the true elevation observed, or 2140 feet below the summit of Chimboraço.

Calculation without Logarithms.

These calculations are performed by the help of logarithms. It is desirable, however, to approximate at least to barometrical measurements without such aid. A very simple rule for this object has been given by Professor Leslie in his *Elements of Geometry*. Since Log. $\frac{a}{b} = 2\text{ M}\left(\frac{a-b}{a+b} + \frac{1}{3}\left(\frac{a-b}{a+b}\right)^3 + \frac{1}{5}\left(\frac{a-b}{a+b}\right)^5 \text{ \&c.}\right)$, where M denotes the modulus of the logarithmic system. When a approaches to b, the lower terms may be rejected without sensible error, or Log. $\frac{a}{b} = 2\text{ M}\left(\frac{a-b}{a+b}\right)$, very nearly. Wherefore, in reference to our atmosphere, the modulus is expressed by the equiponderant column of homogeneous fluid, or 60,000 × .4342945 = 26,058 feet, or only 26,000 in round numbers; whence, *as the sum of the mercurial columns is to their difference, so is the constant number* 52,000 *feet to the approximate height.* Let General Roy's observation on Snowdon be resumed as an example: The analogy is 30.091 + 26.439 : 30.091—26.439, or 56.530 : 3.652 :: 52000 : 3,359, the approximate elevation, differing very little from the logarithmic result.

This mode of calculation may be deemed sufficiently accurate for determining any altitude that exceeds not 5000 feet. But it will extend to greater elevations, if the second term of the series be likewise taken; which is done by striking off three figures, and cubing the half of this number. Thus, resuming the mensuration of Chimboraço; 44.895 : 15.105 :: 52,000 : 17,496, and $(8.75)^3 = 670$, making together 18,166 for a nearer approximation.

Barometric Scale.

The calculation of barometrical measurements, including the corrections required, is rendered most easy and expeditious by means of a sliding rule made by Mr Cary, optician in London. This small instrument should always go along with mountain barometers, and it will be found a very agreeable companion to every geological traveller.

But portable barometers, in spite of every precaution, are yet so liable to be broken or deranged, that other auxiliary methods are desirable for ascertaining distant elevations. In this view, the variation of the boiling point of water was proposed by Fahrenheit, as far back as the year 1724, the idea having occurred to him, as it had done before to Amontons, while engaged with experiments to perfect his thermometer. Little regard, however, seems to have been paid to the sugges-

Barometrical Measurements.

tion, till De Luc and Saussure made a series of observations on the heat of ebullition at different elevations above the surface. About thirty years since, Cavallo attempted to revive the scheme of Fahrenheit, but experienced much difficulty in preventing the irregular starts of the thermometer plunged in boiling water. The best and surest way of examining the heat of ebullition, is to suspend the bulb of the thermometer in the confined steam, as it rises from the water; and this mode, we understand, has very lately been resumed, with great prospect of success, by the Reverend Mr Wollaston.

Temperature of Boiling Water applied to the Mensuration of Heights.

The heat at which water boils, or passes into the form of steam, depends on the weight of the superincumbent atmosphere. By diminishing this pressure, the point of ebullition is always lowered. It appears that, while the boiling heat sinks by equal differences, the corresponding atmospheric pressure decreases exactly, or at least extremely nearly, in a geometrical progression; it being found that every time such pressure is reduced to one half, the temperature of boiling water suffers a regular diminution of about eighteen centesimal degrees. This beautiful relation assimilates with the law which connects the density and elevation of the successive strata of the atmosphere. The interval noticed between the boiling points at two distinct stations must be proportional to their difference of altitude above the level of the sea. We have, therefore, only to determine the coefficient or constant multiplier; which may be discovered either from an experiment under the rarefied receiver of an air-pump, or from an actual observation performed at the bottom and on the top of some lofty mountain. We shall prefer at present the observation made by Saussure on the summit of Mont Blanc. This diligent philosopher found, by means of a very delicate thermometer constructed on purpose, that water which boiled at 101°.62 in the plain below when the barometer stood at 30.534 English inches, boiled at 86°.24 on the top of that mountain, while the barometer had sunk to 17.136. Wherefore the distance between the points of ebullition, or 15.38 centesimal degrees, must correspond to an approximate elevation of 15,050 feet; which gives $978\frac{1}{2}$ feet of ascent for each degree, supposing the mean temperature of the atmospheric column to be that of congelation. But it will be more convenient to assume 1000 for the constant multiplier, which corresponds to the temperature of $5\frac{1}{2}°$.

To reduce this very simple result into practice, it would be requisite to have a thermometer with a fine capillary bore, and nicely constructed, the stem six or eight inches long, and bearing ten or a few more degrees from the boiling point; these degrees to be divided into twenty or perhaps fifty equal parts engraved on the tube, which should be rather thick, and terminating in a bulb of about half an inch diameter. This thermometer, being fitted with a brass ring two inches above the bulb, should screw into the narrow neck of a small copper flask, which holds some water, but has a hole perforated near the top for allowing the steam to escape. The water may be made to boil by the application of a lamp. The difference between the indications of the thermometers at the two stations being multiplied by a thousand feet, will give the elevation corresponding to a temperature of $5\frac{1}{2}°$. The correction for the actual mean temperature can easily be applied. If a more correct coefficient be afterwards determined, the same thousand, retained as a multiplier, may easily be adapted to another temperature.

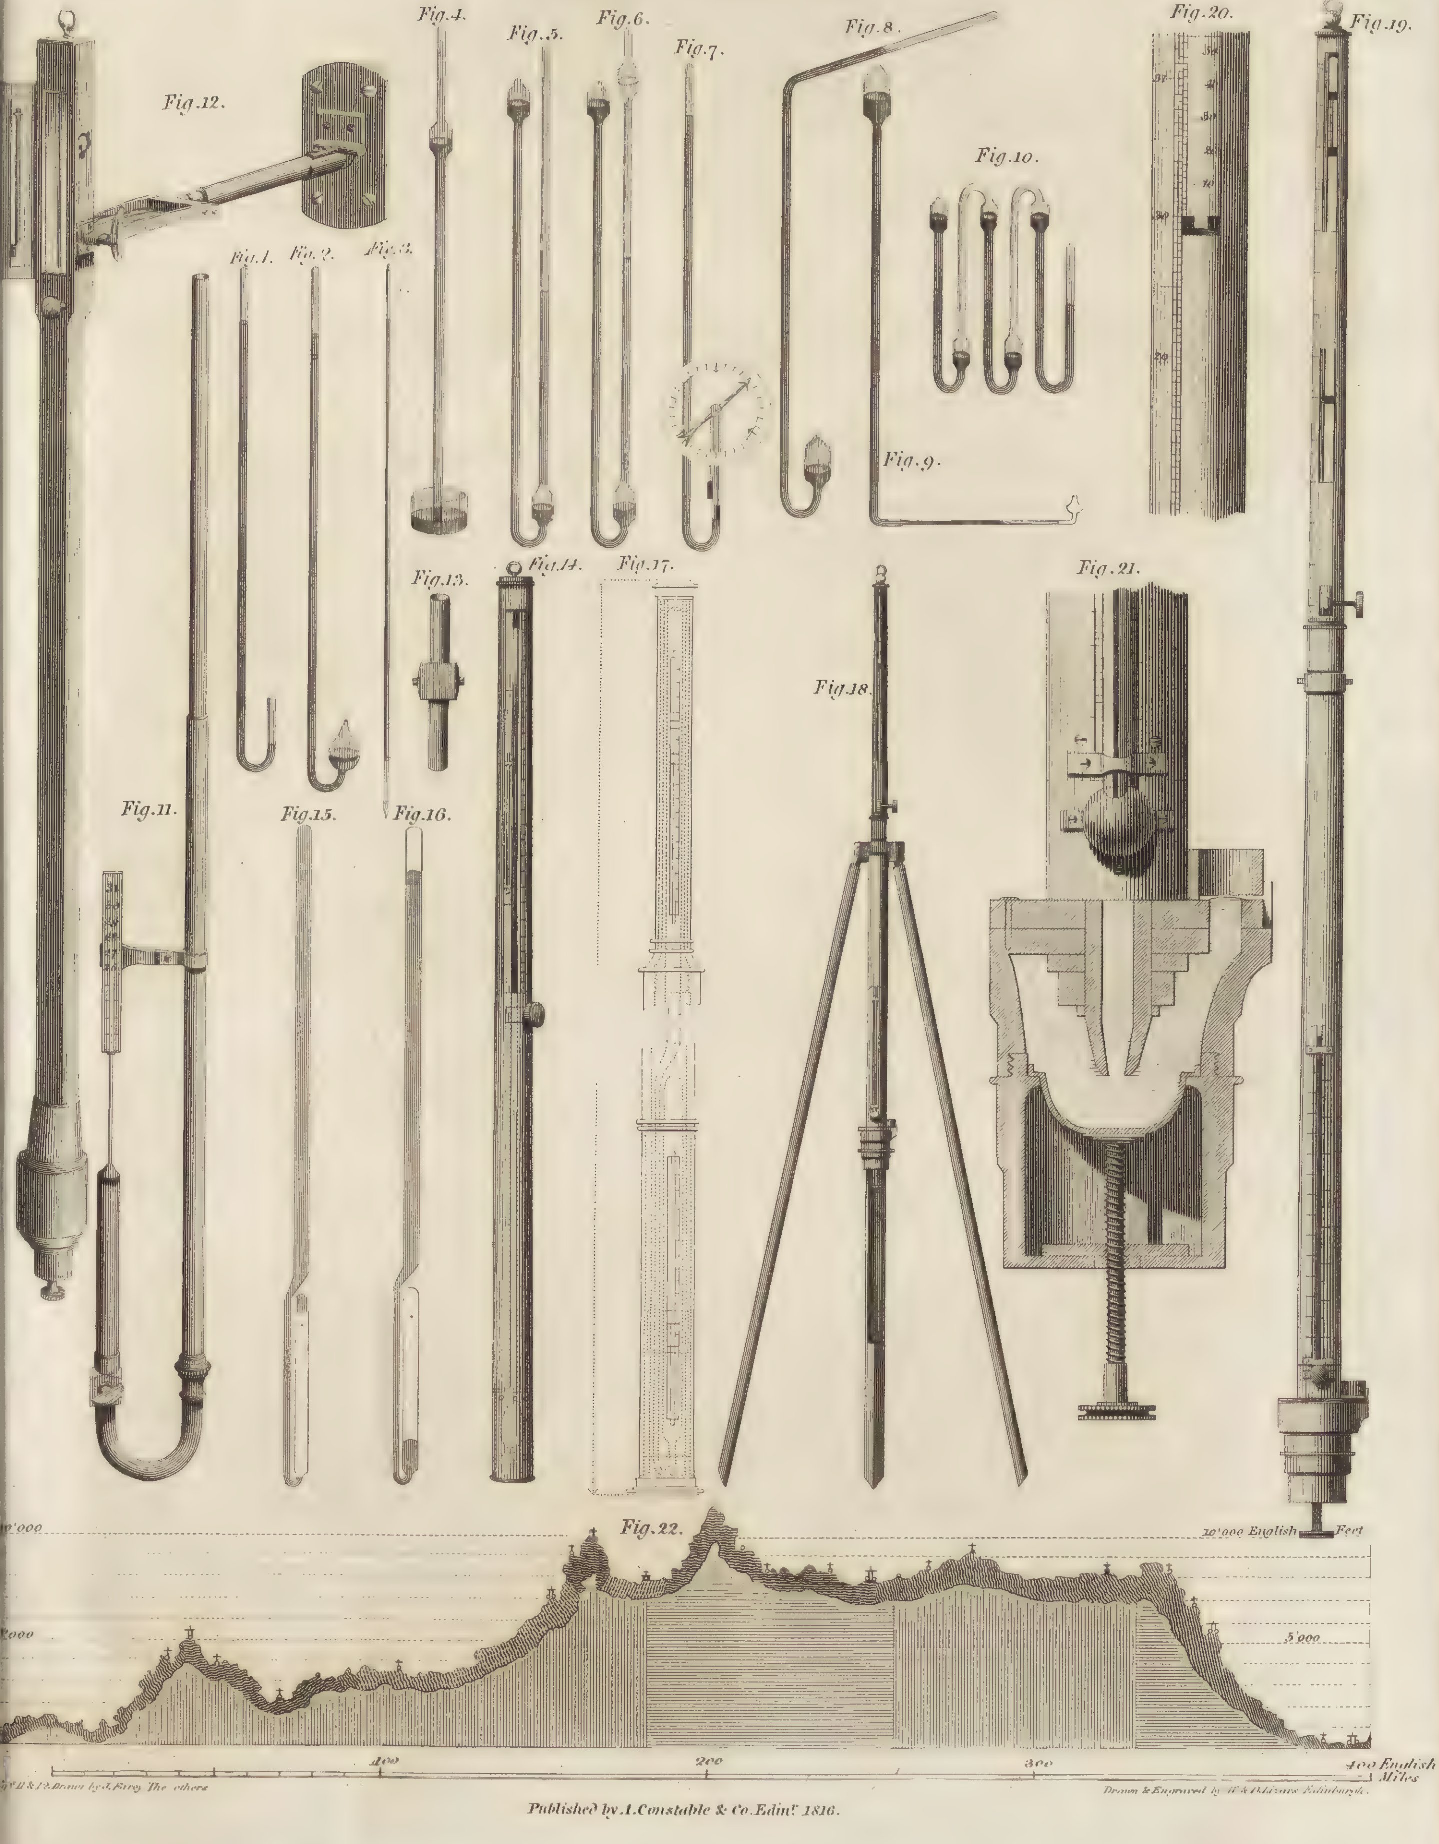
Mode of tracing Vertical Sections.

This method of measuring elevations on the surface of the globe is, therefore, capable of great improvement, and might be employed with advantage in a variety of cases where observations with the barometer are not easily obtained. Its application would be most important to physical geography, in ascertaining the capital points for tracing the outline of the profile or vertical section of any country. The common maps, which exhibit mere superficial extension, are quite insufficient to represent the great features of nature, since the climate and productions of any place depend as much on its elevation above the sea as its latitude. Scientific travellers have accordingly turned their attention of late years to the framing of vertical sections. As a specimen, we give in fig. 22, from Humboldt's *Geography of Plants*, a section across the American Continent, one of the best and most interesting that has yet appeared. It consists, in fact, of four combined sections, traversing through an extent of 425 miles. The line begins at Acapulco on the shore of the Pacific Ocean, and runs 195 miles, about a point of the compass towards the East of North, to the city of Mexico; then 80 miles, a point to the South of East, to La Puebla de los Angeles; again it holds a North-East direction of 70 miles, to the Cruz Blanca; and finally bends 80 miles East by South, to Vera Cruz, on the coast of the Atlantic. A scale of altitudes is annexed, which shows the vast elevation of the table-land of Mexico. An attempt is likewise made in this profile to give some idea of the geological structure of the external crust. *Limestone* is represented by straight lines slightly inclined from the horizontal position: *Basalt*, by straight lines slightly reclined from the perpendicular: *Porphyry*, by waved lines somewhat reclined: *Granite*, by confused hatches: *Amygdaloid*, by confused points.

The Caspian below the level of the Ocean.

By this mode of distant levelling, a very interesting discovery, in another quarter of our globe, has been recently made by Engelhardt and Parrot, two Prussian travellers. They proceeded, on the 13th July 1814, from the mouth of the Kuban, at the island of Taman, on the Black Sea; and, examining carefully every day the state of the barometer, they advanced with fifty-one observations, the distance of 990 wersts, or 711 English miles, to the mouth of the Terek, on the margin of the Caspian Sea. Similar observations were repeated and multiplied on their return. From a diligent comparison of the whole, it follows that the Caspian is 334 English feet below the level of the Black Sea. That the Caspian really occupies a lower level than the Ocean, had been suspected before, from a comparison of some registers of barometers kept at St Petersburg, and on the borders of that inland sea; but the last observation places the question beyond all doubt. It farther appears, that within 250 wersts, or 189 miles, of the Caspian, the country is already depressed to the level of the Ocean, leaving, therefore, an immense bason, from which the waters are supposed to have retired by a subterranean percolation. (D.)

BAROMETER. PLATE XXXII.



Figs. 11 & 12. Drawn by J. Farey. The others Drawn & Engraved by W. & D. Lizars Edinburgh.

Published by A. Constable & Co. Edinr. 1816.

Barracks. Historical Notices.

BARRACKS. Till the middle of the year 1792, when there was a prospect of a war with revolutionary France, and the British ministry were apprehensive of disturbances in this country, barracks were neither very numerous, nor were they under the control and management of a separate and peculiar Board. Till that time, they were built under the authority and directions of the Board of Ordnance, by whom they were supplied with bedding and the necessary utensils. Any extra articles that were requisite were supplied by the secretary at war. In 1792, orders were given by the ministry to build cavalry barracks with the utmost despatch, and the deputy-adjutant-general was directed to superintend the building and fitting them up. In January 1793, he was appointed superintendant-general of barracks; and, on the 1st of May that year, the King's warrant was issued for their regulation. Greater powers were given to the superintendant-general in the year 1794; but as these seemed to interfere with the duties and powers of the Board of Ordnance, a new warrant was issued in the year 1795, defining and limiting the respective duties and powers of the Board of Ordnance, and the superintendant-general, or barrack-master-general, as he was now called. In the year 1796, the barrack-office establishment consisted of a barrack-master-general, with two clerks; a deputy-barrack-master-general; an assistant-barrack-master-general, with three clerks; an accountant, with five clerks; an assistant-barrack-master-general for the general inspection of barracks, and six other assistant-barrack-masters-general for the particular inspection of barracks in different districts; five clerks for general business; one assistant-barrack-master-general for the building branch; one checking clerk, and seven other clerks; two architects and surveyors; one assistant-barrack-master-general in North Britain; with two assistants and clerks; one treasurer; and three other assistant-barrack-masters-general for general duties, and visiting barracks. The salaries and extra pay of these officers amounted, in 1796, to L. 9524, 17s. 2d. The establishment was afterwards considerably increased, in proportion as the number of barracks throughout the kingdom increased, and by the creation of some new officers, among whom was a law clerk. In 1806, the salaries amounted to L. 19,329, 4s. 10d.

Official Reports respecting Barracks.

During this year, the commissioners of military inquiry began their duties; and their first reports were on the subject of the barrack establishment: In the arrangement of this establishment, and in the mode in which its duties were performed, particularly with respect to the supplies of coals, &c. to the different barracks, and the contracts for building them, they pointed out many things that were highly objectionable; and concluded their reports by recommending that the offices of barrack-master-general, and deputy-barrack-master-general, should be totally abolished, and that the superintendence of the barrack establishment should be vested in commissioners. This suggestion, and some others relative to the mode of transacting the business of the department, and preventing useless and extravagant expenditure, have been followed; and the barrack establishment is now under the direction of four commissioners, one of whom is generally a military man. The mode of writing letters in this public department is deserving of notice and imitation, as securing despatch and accuracy. A sheet of paper being folded in the middle, officers of the department, who address the barrack-office, write their letters on the left side; and, along with the original letter, send a duplicate in the same form, and signed also. On the blank side of the duplicate is written the official answer from the barrack-office which is sent; and, on the original letter, which is preserved in the office, is copied the answer: each party has thus an exact copy of the whole correspondence.

New Arrangement.

Clause in the Defence Act respecting Barracks.

As it frequently happened, that it was absolutely necessary to build barracks on an emergency, when there was no time to summon a jury to value the land before the commencement of the building, and as most persons were averse to have barracks near their dwelling-houses, or even on their property, Government was often obliged to pay an extravagant price for the land which they needed for their erection; in order to remedy this evil, it was provided by the act, usually called the defence act, 43d Geo. III. cap. 55, that Justices of the Peace might put any general officer into the possession of such ground as he might deem fit for the erection of barracks;—the value of it to be settled afterwards by a jury;—provided, however, the necessity for such ground was certified by the Lord-Lieutenant, or two Deputy-Lieutenants of the county.

Barracks throughout the country are more immediately under the management and care of the assistant-barrack-masters-general, and the resident barrack-masters; the former are attached to districts; the latter to particular barracks. The following are the districts in Great Britain:

Barrack Districts.

1. Northern, containing Northumberland, Cumberland, Westmoreland, and Durham.
2. York, containing Yorkshire.
3. Eastern, containing Norfolk, Suffolk, Cambridge, Huntingdonshire, and all Essex, except Tilbury-fort.
4. Southern, containing Kent, Tilbury-fort, and Sussex.
5. South-western, containing Hampshire and Dorsetshire.
6. Isle of Wight.
7. Western, containing Devonshire, Cornwall, and Somerset.
8. Severn, containing Gloucestershire, Worcestershire, Herefordshire, Monmouthshire, and South Wales.
9. North-western, containing Cheshire, Shropshire, Lancashire, North Wales, and the Isle of Man.
10. London.
11. Home, containing Middlesex, Surrey, Hertfordshire, and part of Kent.
12. North-inland, containing Derbyshire, Nottinghamshire, Staffordshire, Warwickshire, Leicester shire, and Rutlandshire.
13. South-inland, containing Bedfordshire, Northamptonshire, Oxfordshire, and Buckinghamshire.
14. Jersey, Guernsey, and Alderney.

Barracks.

SCOTLAND.

Northern, containing Caithness, Sutherland, Ross-shire, Inverness-shire, Nairnshire, Morayshire, and Banffshire.

Western, containing Aberdeenshire, Argyleshire, Ayrshire, Bute, Kincardineshire, Lanarkshire, Renfrewshire, and Wigtonshire.

Centre, containing Angus-shire, Clackmannanshire, Dunbartonshire, Fifeshire, Kinross-shire, Perthshire, and Stirlingshire.

Southern, containing the Lothians, Berwickshire, Peebles-shire, Selkirkshire, Roxburghshire, and Dumfries-shire.

Number of Barracks in 1805.

On the 14th of July 1805, there were in Great Britain and Jersey, &c.

Established barracks of brick and stone	84
——— of wood	12
Temporary barracks	75
——— rented	41
	212

The annual rents at this time amounted to L. 40,231. The whole of these barracks were calculated to accommodate nearly 100,000 foot and 15,000 cavalry. In the cavalry barracks, field-officers have two rooms each; captains one; subalterns, staff, and quarter-masters, one; serjeants of each troop of dragoons, and corporals of each troop of horse, one; eight rank and file one among them; and two rooms are allowed for the officers' mess. In infantry barracks, field-officers are allowed two each; captains one; one is allotted to two subalterns; the staff has one; twelve non-commissioned officers and private men, one among them; the serjeant-major and quarter-master-serjeant, one; and two are allotted for the officers' mess. The barracks are supplied by the barrack-office with beds, bedding, sheets, blankets, towels, house and stable utensils, coals and candles: beer was formerly supplied, but now an allowance is made instead of it. Forage is supplied by the commissariot.

Accommodations and Supplies.

The expence of erecting barracks must of course greatly depend on the price of materials at the time, and, in some measure, on the part of the kingdom where they are erected. In the year 1805, permanent barracks for a battalion of 800 men, in the south of England, cost L. 37,000; and barracks for 1200 infantry and 400 cavalry L. 60,000.

Expence from 1792 to 1804.

The following statement exhibits the several particulars of the total expence incurred by the nation for barracks, and the barrack-office, in Great Britain, between the 25th of December 1792, and the 10th of November 1804:

Buildings and purchases of land,	L. 3,930,223	5	8
Forage,	846,246	7	10
Beer,	643,030	9	6
Coals, candles, furniture, rents, repairs, supplied by barrack-masters, and salaries,	1,685,487	8	0
Office-establishment,	256,129	10	4
Fees at War-office,	80,346	3	6
Insurance,	1,519	2	2
Additional rents,	36,860	13	5
Lodging-money to officers,	139,582	16	0
Engines,	11,866	0	5
Bedding, furniture, &c. issued by the Barrack-office, and in store,	1,357,215	7	3
Miscellaneous,	35,498	4	8
Total,	L. 9,024,005	8	9

Barracks ‖ Barry.

Present Expence.

The annual expence, during the last war, varied from L. 350,000 to L. 500,000; in the year 1814, it was L. 309,826. The peace estimate for 1816 is L. 173,500. In Ireland, where barracks are more numerous, the expence, in 1814, was L. 360,515, and the peace estimate for 1816 is L. 213,000.

See first, second, third, and fourth *Reports of the Commissioners of Military Inquiry*, 1806; and the *Finance Reports* and *Estimates* laid before Parliament for the years 1814 and 1816. (c.)

BARRY (JAMES), an eminent painter, was born at Cork, in Ireland, October 11, 1741. His father had been a builder, and at one time of his life, a coasting trader between the two countries of England and Ireland. To this business of a trader was James destined, and he actually made, when a boy, several voyages; but these voyages being forced upon him, he on one occasion ran away from the ship, and on others discovered such an aversion to the life and habits of a sailor, as to induce his father to quit all hopes of him in this line, and to suffer him to pursue his inclinations, which led him to drawing and study. When on board his father's vessel, instead of handling sails and ropes, and climbing the mast, he was generally occupied with a piece of black chalk, sketching the coast, or drawing figures, as his fancy directed him. When his father found that the idea of making a sailor of him must be given up, he permitted him to acquire as much instruction as the schools of Cork afforded; but long retained his aversion to the chalk drawings, with which the floors and walls of the house were covered; the boy being always engaged in some attempt at large figures, and early catching at the means of representing action, attitude, and passion. It was at a very early period of his life that some bookseller in Ireland, undertaking to reprint a set of fables or emblems, young Barry offered to furnish the drawings, and, as it is believed, helped to etch the engravings, such as they were. At the schools in Cork, which he was sent to, he was distinguished by his parts and industry above his school-fellows; his habits differed from those of ordinary boys, as he seldom mixed in their games or amusements, but at those times stole off to his own room, where he worked at his pencil, or was studying some book that he had borrowed or bought. He would spend whole nights in this manner at his studies, to the alarm of his mother, who dreaded his injuring his health or setting fire to the house, and who often kept up his sister or the servant to watch him. His allowance of money he spent in buying books or candles to read by; he sometimes locked himself up in his room for days, and seldom slept upon his bed, or else made it so hard as to take away the temptation or luxury of lying long in it. Perhaps the unsocial and ascetic turn of his temper,

Barry.

which thus early manifested itself, might be remarked as the source both of the misfortunes of his life, and of the defects of his genius. Common humanity, a sense of pleasure, and a sympathy with the feelings of those around us, is not more necessary to success in life, than it probably is to success in the fine arts. Few things can be more fatal to the artist than this sort of indifference to the common pleasures and pursuits of life. If affected, it is bad; if real and constitutional, it is even worse. It stuck to poor Barry to the last. It is not to be understood that, at this period of his life, he led the life of an absolute recluse, for he could and did occasionally join in any feats going on in the neighbourhood, and was not behind other boys in such pastimes and mischief as boys are usually fond of. An adventure which happened to him about this time, and which left a strong impression on his mind, is worth mentioning here. In one of his rambles in the neighbourhood, he entered, one winter's evening, an old, and, as he thought, an uninhabited house, situate in a narrow bye-lane in the city of Cork. The house was without doors or windows; but curiosity impelled him to enter, and, after mounting a rotten staircase, which conducted to empty rooms on different floors, he arrived at the garret, where he could just discern, by the glimmering light of a few embers, two old and emaciated figures, broken by age, disease, and want, sitting beside each other, in the act, as far as their palsied efforts would permit, of tearing each other's faces; not a word being uttered by either, but with the most horrible grimaces that malice could invent. They took no notice of his entrance, but went on with their deeds of mutual hate, which made such an impression on the boy that he ran down stairs, making his own reflections, which he afterwards found verified through life, that man and all animals are malicious and cruel in proportion as they are impotent; and that age and poverty, two of the worst evils in human life, almost always add to the calamities inherent in them by arts of their own creating. In general, his great desire to improve his mind led him to seek the society of educated men; who were not averse to receive him, seeing his active and inquisitive disposition, and his seriousness of manner, couched under a garb the plainest and coarsest; for he adopted this kind of attire from his childhood, not from affectation, but from an indifference to all dress. Having a retentive memory, he profited by his own reading, and by the conversation of others, who directed him also in the choice of books. As his finances were too low to make many purchases, he borrowed books from his friends, and was in the practice of making large extracts from such as he particularly liked, and sometimes even of copying out the whole book, of which several specimens were found among his papers, written in a stiff schoolboy's hand. As his industry was excessive, his advances in the acquisition of knowledge were rapid, and he was regarded as a prodigy by his school-fellows. His mother being a zealous Catholic, the son could not avoid mixing at times in the company of priests resident at Cork, who pointed out to him books of polemical divinity, of which he became a great reader, and for which he retained a strong bias during his lifetime. He was said at one time to have been destined for the priesthood, but for this report there is no authority. He, however, always continued a Catholic, and in the decline of life manifested rather a bigoted attachment to the religion of his early choice. For a short interval he had a little wavering in his belief of revealed religion in general; but a conversation with Mr Edmund Burke put an end to this levity. A book which Mr Burke lent him, and which settled his mind on this subject, was Bishop Butler's *Analogy;* and as a suitable reward, he has placed this Prelate in the group of divines, in his picture of Elysium.

Barry.

About the age of seventeen he first attempted oil paintings; and between that and the age of twenty-two, when he first went to Dublin, he produced several large ones, which decorated his father's house, and represented subjects not often handled by young men; such as Æneas escaping with his family from the flames of Troy; Susanna and the Elders; Daniel in the Lion's Den, &c. At this period, he also produced the picture which first drew him into public notice, launched him on an ampler theatre than his native town of Cork afforded, and, above all, gained him the acquaintance and patronage of Mr Burke. This picture was founded on an old tradition of the landing of St Patrick on the sea-coast of Cashel, and of the conversion and baptism of the king of that district by the patron saint of Ireland. The priest, in the act of baptizing his new convert, inadvertently strikes the spear of the crozier in the foot of the monarch. The holy father, absorbed in the duties of his office, does not perceive what he has done, and the king, without interrupting the ceremony, bears the pain with immoveable fortitude. This incident, together with the gestures and expressions of the attendants, certainly formed a good subject for an historical picture; and Mr Barry's manner of treating it was such as to ensure him the applause and admiration of the connoisseurs of the metropolis of the sister kingdom, where it was exhibited in 1762 or 1763. Mr Barry took this picture with him to Dublin; and afterwards going to the exhibition room, being delighted with the encomiums it received from the spectators, he could not refrain from making himself known as the painter. His pretensions were treated with great contempt by the company, and Barry burst into tears of anger and vexation. But the incredulity of his hearers was a compliment paid to the real or supposed excellence of his painting. It appears that a Dr Sleigh, a physician of Cork, and a sensible and amiable man, was first instrumental in introducing young Barry to the notice of Mr Burke. During their early acquaintance, having fallen into a dispute on the subject of taste, Barry quoted a passage in support of his opinion from the *Essay on the Sublime and Beautiful,* which had been just then published anonymously, and which Barry, in his youthful admiration of it, had, it seems, transcribed entire. Burke affected to treat this work as a theoretical romance, of no authority whatever, which threw Barry into such a rage in its defence, that Mr Burke thought it necessary to appease him by owning himself to be the author. The scene ended in Barry's

Barry.

running to embrace him, and showing him the copy of the work, which he had been at the pains to transcribe. He passed his time in Dublin in reading, drawing, and society. While he resided here, an anecdote is preserved of him, which marks the character of the man. He had been enticed by his companions several times to carousings at a tavern, and one night, as he wandered home by himself, a thought struck him of the frivolity and viciousness of thus mis-spending his time : the fault, he imagined, lay in his money, and, therefore, without more ado, in order to avoid the morrow's temptation, he threw the whole of his wealth, which perhaps amounted to no great sum, into the Liffey, and locked himself up at his favourite pursuits. After a residence of seven or eight months in Dublin, an opportunity offered of accompanying some part of Mr Burke's family to London, which he eagerly embraced. This took place sometime in the year 1764, when he was twenty-three years of age, and with one of those advantages which do not always fall to the lot of young artists on their arrival in the British capital, that of being recommended to the acquaintance of the most eminent men in the profession by the persuasive eloquence of a man who, to genius in himself, added the rare and noble quality of encouraging it in others ; this was Mr Burke, who lost no time, not merely in making Barry known, but in procuring for him the first of all objects to an inexperienced and destitute young artist, employment. This employment was chiefly that of copying in oil drawings by Mr Stewart, better known by the name of Athenian Stewart ; and whether it suited the ambition of Barry or not, to be at this kind of labour, yet there can be no doubt that he profited by his connection with such a man as Stewart, and had full leisure to cast his eye about, and to improve by the general aspect of art and artists that occupied the period.

Mr Burke and his other friends thinking it important that he should be introduced to a wider and nobler school of art than this country afforded, now came forward with the means necessary to accomplish this object ; and in the latter end of 1765 Mr Barry proceeded to the Continent, where he remained till the beginning of 1771, studying his art with an enthusiasm which seemed to augur the highest success, and making observations on the different *chef d'œuvres* of Italy with equal independence of judgment and nicety of discrimination. He was supported during this period by the friendly liberality of the Burke family (Edmund, William, and Richard), who allowed him forty pounds a-year for his necessary expenditure, besides occasional remittances for particular purposes. He proceeded first to Paris, then to Rome, where he remained upwards of three years, from thence to Florence and Bologna, and home through Venice. His letters to the Burkes, giving an account of Michael Angelo, Raphael, Titian, and Leonardo da Vinci, show a complete insight into the characteristic merits of their works, and would make us wonder (if the case were at all singular) how he could enter with such force, delicacy, and feeling, into excellencies of which he never transplanted an atom into his own works. He saw, felt, and *wrote ;* his impressions were profound and refined, but the expression of them must be instantaneous, such as gave the results of them with a stroke of the pen, as they were received by a glance of the eye, and he could not wait for the slow process of the pencil for embodying his conceptions in the necessary details of his own art. It was his desire to make the ideas and language of painting coinstantaneous,—to express abstract results by abstract mechanical means (a thing impossible),—to stamp the idea in his mind at once upon the canvass, without knowledge of its parts, without labour, without patience, without a moment's time or thought intervening between what he wished to do and its being done, that was perhaps the principal obstacle to his ever attaining a degree of excellence in his profession at all proportioned either to his ambition or his genius. It is probable, that, as his hand had not the patience to give the details of objects, his eye, from the same habit of mind, had not the power to analyze them. It is possible, however, to see the results without the same laborious process that is necessary to convey them ; for the eye sees faster than the hand can move.

We suspect Mr Barry did not succeed very well in copying the pictures he so well describes ; because he appears to have copied but few, only one of Raphael, as far as we can find, and three from Titian, whom he justly considered as the model of colouring, and as more perfect in that department of the art than either Raphael or Michael Angelo were in theirs, expression and form, the highest excellence in which he conceives to have been possessed only by the ancients. In copying from the antique, however, he manifested the same aversion to labour, or to that kind of labour which, by showing us our defects, compels us to make exertions to remedy them. He made all his drawings from the antique, by means of a *delineator*, that is, a mechanical instrument, to save the trouble of acquiring a knowledge both of form and proportion. In this manner, equally gratifying to his indolence and his self-love, he is stated to have made numberless sketches of the antique statues, of all sizes, and in all directions, carefully noting down on his sketch-paper their several measurements and proportions.

The consequences are before us in his pictures ; namely, that all those of his figures which he took from these memorandums are deficient in everything but form, and that all the others are equally deficient in form and everything else. If he did not employ his pencil properly, or enough, in copying from the models he saw, he employed his thoughts and his pen about them with indefatigable zeal and spirit. He talked well about them ; he wrote well about them ; he made researches into all the collateral branches of art and knowledge, sculpture, architecture, cameos, seals, and intaglios. There is a long letter of his, addressed to Mr Burke, on the origin of the Gothic style of architecture, written, as it should seem, to convince his friend and patron of his industry in neglecting his proper business. Soon after his arrival at Rome, he became embroiled with the whole tribe of connoisseurs, painters, and patrons there, whether native or foreign, on subjects of *virtù ;* and he continued in this state of hostility with those

Barry.

around him while he staid there, and, indeed, to the end of his life. One might be tempted to suppose, that Barry chiefly studied his art as a subject to employ his dialectics upon. On this unfortunate disposition of his to wrangling and controversy, as it was likely to affect his progress in his art and his progress in life, he received some most judicious advice from Sir Joshua Reynolds and Mr Burke, his answers to which show an admirable self-ignorance. On his irritable denunciations of the practices and tricks of the Italian picture-dealers, Mr Burke makes a reflection well deserving of attention. "In particular, you may be assured that the traffic in antiquity, and all the enthusiasm, folly, and fraud, which may be in it, *never did, nor never can hurt the merit of living artists.* Quite the contrary, in my opinion; for I have ever observed, that, whatever it be that turns the minds of men to anything relative to the arts, even the most remotely so, brings artists more and more into credit and repute; and though, now and then, the mere broker and dealer in such things runs away with a great deal of profit, yet, in the end, ingenious men will find themselves gainers by the dispositions which are nourished and diffused in the world by such pursuits." Mr Barry painted two pictures while abroad, his Adam and Eve and his Philoctetes. The first of these he sent home as a specimen of his progress in the art. It does not appear to have given much satisfaction. His Philoctetes he brought home with him. It is a most wretched, coarse, unclassical performance, the directly opposite to all that he thought it to be. During his stay at Rome, he made an excursion to Naples, and was highly delighted with the collections of art there. All the time he was abroad, Mr Burke and his brothers not only were punctual in their remittances to him, but kept up a most friendly and cordial correspondence. On one occasion, owing to the delay of a letter, a bill which Barry had presented to a banker was dishonoured. This detained Barry for some time at the place where he was in very awkward circumstances, and he had thoughts of getting rid of his chagrin and of his prospects in life at once, by running away and turning friar. For some time previous to his return to England, Mr Hamilton (afterwards Sir William) appears to have been almost the only person with whom he kept up any intimacy. It was on his return home through Milan that he witnessed, and has recorded with due reprobation, the destruction of Leonardo's Last Supper, which two bungling artists were employed to paint over by order of one Count de Firmian, the secretary of state.

In the spring of 1771, Mr Barry arrived in England, after an absence of five years. He soon after produced his picture of Venus, which has been compared to the Galatea of Raphael, the Venus of Titian, and the Venus of Medicis, without reason. Mr Barry flattered himself that he had surpassed the famous statue of that name, by avoiding the appearance of *maternity* in it. There is an engraving of it by Mr Valentine Green. In 1773, he exhibited his Jupiter and Juno on Mount Ida, which was much praised by some critics of that day. His Death of General Wolfe was considered as a falling off from his great style of art, which consisted in painting Greek subjects, and it accordingly is said to "have obtained no praise." His fondness for Greek costume was assigned by his admirers as the cause of his reluctance to paint portraits; as if the coat was of more importance than the face. His fastidiousness, in this respect, and his frequent excuses, or blunt refusals, to go on with a portrait of Mr Burke, which he had begun, caused a misunderstanding with that gentleman, which does not appear to have been ever entirely made up. The difference between them is said to have been widened by Burke's growing intimacy with Sir Joshua, and by Barry's feeling some little jealousy of the fame and fortune of his rival *in an humbler walk of the art.* He, about the same time, painted a pair of classical subjects, Mercury inventing the lyre, and Narcissus looking at himself in the water, the last suggested to him by Mr Burke. He also painted an historical picture of Chiron and Achilles, and another of the story of Stratonice, for which last the Duke of Richmond gave him a hundred guineas. In 1773, there was a plan in contemplation for our artists to decorate the inside of St Paul's with historical and sacred subjects; but this plan fell to the ground, from its not meeting with the concurrence of the Bishop of London and the Archbishop of Canterbury, to the no small mortification of Barry, who had fixed upon the subject he was to paint,—the rejection of Christ by the Jews when Pilate proposes his release. In 1775, he published *An Inquiry into the real and imaginary Obstructions to the Acquisition of the Arts in England*, vindicating the capacity of the English for the fine arts, and tracing their slow progress hitherto to the Reformation; to political and civil dissensions; and, lastly, to the general turn of the public mind to mechanics, manufactures, and commerce. In the year 1774, shortly after the failure of the scheme for decorating St Paul's, a proposal was made, through Mr Valentine Green, to the same artists, Reynolds, West, Cipriani, Barry, &c. for ornamenting the great room of the Society for the *Encouragement of Arts, Manufactures, and Commerce*, in the Adelphi, with historical and allegorical paintings. This proposal was, at the time, rejected by the artists themselves; but, in 1777, Mr Barry made an offer to paint the whole himself, on condition of being allowed the choice of his subjects, and being paid the expence of canvass, paints, and models, by the Society. This offer was accepted, and he finished the series of pictures at the end of seven years, instead of two, which he had proposed to himself, but with entire satisfaction to the members of the Society, for whom it was intended, and who conducted themselves to him with liberality throughout. They granted him two exhibitions, and at different periods voted him 50 guineas, their gold medal, and again 200 guineas, and a seat among them. Dr Johnson remarked, when he saw the pictures, that, "whatever the hand had done, the head had done its part." There was an excellent anonymous criticism, supposed to be by Mr Burke, published on them, in answer to some remarks put forth by Barry, in his descriptive catalogue, on the *ideal* style of art, and the necessity of size to gran-

Barry.

deur. His notions on both these subjects are very ably controverted, and, indeed, they are the rock on which Barry's genius split. It would be curious if Mr Burke were the author of these strictures; for it is not improbable that Barry was led into the last error, here deprecated, by that author's *Essay on the Sublime and Beautiful.* The series consists of six pictures, showing the progress of human culture. The first represents Orpheus taming the savages by his lyre. The figure of Orpheus himself is more like a drunken bacchanal than an inspired poet or lawgiver. The only part of this picture which is valuable is the background, in one part of which a lion is seen ready to dart upon a family group milking near a cave, and, in another, a tyger is pursuing a horse. There is certainly a scope of thought and picturesque invention, in thus showing indirectly the protection which civilization extends, as it were, over both man and animals. The second picture is a Grecian harvest, which has nothing Grecian in it. But we cannot apply this censure to the third picture of the Olympic games, some of the figures in which, and the principal group, are exceedingly graceful, classical, and finely conceived. This picture is the only proof Mr Barry has left upon canvass that he was not utterly insensible to the beauties of the art. The figure of the young man on horseback really reminds the spectator of some of the Elgin marbles; and the outlines of the two youthful victors at the games, supporting their father on their shoulders, are excellent. The colouring is, however, as bald and wretched in this picture as the rest, and there is a great want of expression. The fourth picture is the triumph of commerce, with Dr Burney swimming in the Thames, with his hair powdered, among naked sea-nymphs. The fifth, the Society of Arts, distributing their annual prizes. And the sixth represents Elysium. This last picture is a collection of caricatured portraits of celebrated individuals of all ages and nations, strangely jumbled together, with a huge allegorical figure of Retribution driving Heresy, Vice, and Atheism, into the infernal regions. The moral design of all these pictures is much better explained in the catalogue than on the canvass; and the artist has added none of the graces of the pencil to it in any of them, with the exception above made. Mr Barry appears, however, to have rested his pretensions to fame as an artist on this work, for he did little afterwards but paltry engravings from himself, and the enormous and totally worthless picture of Pandora in the assembly of the gods. His self-denial, frugality, and fortitude, in the prosecution of his work at the Adelphi, cannot be too much applauded. He has been heard to say, that at the time of his undertaking it, he had only 16s. in his pocket; and that he had often been obliged, after painting all day, to sit up at night to sketch or engrave some design for the printsellers, which was to supply him with his next day's subsistence. In this manner he did his prints of Job, dedicated to Mr Burke, of the Birth of Venus, Polemon, Head of Chatham, King Lear, from the picture painted for the Shakespear gallery, &c. His prints are caricatures even of his pictures: they seem engraved on rotten wood.

Soon after Mr Barry's return from the Continent, he was chosen a member of the Royal Academy; and in 1782, was appointed professor of painting, in the room of Mr Penny, with a salary of L. 30 a-year. The lectures which he delivered from the chair were full of strong sense, and strong advice, both to the students and academicians. Among other things, he insisted much on the necessity of purchasing a collection of pictures by the best masters as models for the students, and proposed several of those in the Orleans collection. This recommendation was not relished by the academicians, who, perhaps, thought their own pictures the best models for their several pupils. Bickerings, jealousies, and quarrels arose, and at length reached such a height, that, in 1799, Mr Barry was expelled from the academy, soon after the appearance of his *Letter to the Dilettanti Society;* a very amusing, but eccentric publication, full of the highest enthusiasm for his art, and the lowest contempt for the living professors of it. In 1800, he undertook a design or drawing to celebrate the union of the two kingdoms of Great Britain and Ireland. The profits of the two exhibitions of the Adelphi pictures are said to have amounted to above L. 500. Lord Romney presented him with 100 guineas for his portrait, which had been copied into one of the pictures, and he had 20 guineas for a head of Mr Hooper. He probably received other sums for portraits introduced into the work. By extreme frugality he contrived, not only to live, but to save money. His house was twice robbed of sums which he kept by him; one of the times (in 1794) of upwards of L. 100; a loss which was made up by the munificence of Lord Radnor, and by that of his friends, the Hollis's. After the loss of his salary, a subscription was set on foot by the Earl of Buchan to relieve him from his difficulties, and to settle him in a larger house to finish his picture of Pandora. The subscription amounted to L. 1000, with which an annuity was bought; but of this he was prevented from enjoying the benefit; for, on the 6th of February 1806, he was seized with a pleuritic fever, and as he neglected medical assistance at first, it was afterwards of no use. After lingering on for a fortnight in considerable pain, but without losing his fortitude of mind, he died on the 22d of the same month. On the 13th of March, the body was taken to the great room of the Society of Arts, and was thence attended, the following day, by a numerous and respectable train of his friends to the cathedral of St Paul's, where it was deposited.

Mr Barry, as an artist, a writer, and a man, was distinguished by great inequality of powers and extreme contradictions in character. He was gross and refined at the same time; violent and urbane; sociable and sullen; inflammable and inert; ardent and phlegmatic; relapsing from enthusiasm into indolence; irritable, headstrong, impatient of restraint; captious in his intercourse with his friends, wavering and desultory in his profession. In his personal habits he was careless of appearances or decency, penurious, slovenly, and squalid. He regarded nothing but his immediate impulses, confirmed into incorrigible ha-

Barry || Barthez.

bits. His pencil was under no control. His eye and his hand seemed to receive a first rude impulse, to which it gave itself up, and paid no regard to any thing else. The strength of the original impetus only drove him farther from his object. His genius constantly flew off in tangents, and came in contact with nature only at salient points. There are two drawings of his from statues of a lion and a lioness at Rome; the nose of the lioness is two strait lines; the ears of the lion two curves, which might be mistaken for horns; as if, after it had taken its first direction, he lost the use of his hand, and his tools worked mechanically and monotonously without his will. His enthusiasm and vigour were exhausted in the conception; the execution was crude and abortive. His writings are a greater acquisition to the art than his paintings. The powers of conversation were what he most excelled in; and the influence which he exercised in this way over all companies where he came, in spite of the coarseness of his dress, and the frequent rudeness of his manner, was great. Take him for all in all, he was a man of whose memory it is impossible to think without admiration as well as regret. (z.)

BARTHEZ (Paul Joseph), one of the most celebrated physicians of the University of Montpellier, equally remarkable for the variety and extent of his erudition, as for the vigour of mind displayed in his abstruse speculations. He was born on the 11th of December 1734, at Montpellier, and received his early education at Narbonne, where his family resided, and afterwards at Toulouse. He soon gave decisive indications of those talents with which nature had endowed him, and which destined him to occupy a distinguished station among the learned men of the age. Ardent in his pursuit of knowledge, and uniting great quickness of apprehension, with a tenacious memory, his progress in every study which he attempted was more than ordinarily rapid; he had a remarkable facility in acquiring languages, and at an early age, had made himself master of the ancient and of several modern ones. He seems to have been for some time uncertain what profession he should follow; but having at length, at the instigation of his father, commenced the study of medicine at Montpellier, in 1750, he pursued it with eagerness, and his success was proportionate to his exertions; for, in 1753, when he had only attained his 19th year, he received his doctor's degree. He afterwards occasionally visited Paris, where he continued to pursue his studies with indefatigable industry; and attracting the notice, not only of those who were following the same objects, but of those who could better appreciate the full extent of his attainments, was admitted to the society, and acquired the friendship of the most distinguished literati of that period. In 1756, he obtained the appointment of physician to the military hospital in Normandy, attached to the army of observation commanded by Marshal Destrées. The zeal and assiduity with which he discharged the duties of his new office were most exemplary. He seemed determined to profit to the utmost by the extensive field of observation which was thus opened to him, and in which he could put to the test of experience the knowledge which he had derived from other sources, and train himself in those habits of nice discrimination of symptoms, and of prompt decision in practice, without which learning is of little avail in the actual exercise of the art. He spent his whole time at the hospital, and often passed the night by the bed-side of his patients. Though naturally of a good constitution, his strength was not commensurate with the ardour of his mind, and the tasks in which he engaged were frequently undertaken without duly appreciating the physical powers necessary for accomplishing them. His health suffered much from the intensity of his application, and he was often very near falling a sacrifice to fevers and other disorders, which he caught from the patients in the hospital, whom he was attending too closely; and he thence became liable ever after to attacks of dysentery and bilious fever.

Barthez.

Many of the observations and inquiries, which he made during this period, were published in the *Memoirs of the Academy of Sciences;* and two of his first productions were crowned by the Academy of Inscriptions. In 1757, his services were required in the medical staff of the army of Westphalia, where he had the rank of consulting physician. On his return to Paris, he contributed several articles to the *Journal des Savants*, and to the *Encyclopédie;* and was, indeed, considered for a time as one of the editors of the former of those works. In 1761, he became candidate for a medical professorship at Montpellier, which he fortunately succeeded in obtaining, and in which his abilities as a teacher soon shone forth with unrivalled lustre. His success was the more honourable, inasmuch as his colleagues, Lamure, Leroy, and Venel, were men of distinguished reputation, and had raised the school to a high pitch of celebrity. But the singular perspicuity, and precision of method, and the peculiar grace and facility of elocution, with which Barthez conveyed to his hearers the ample stores of knowledge of which he was in possession, soon attracted a crowd of auditors, who spread his fame in all directions. He taught in succession all the branches of the medical art; and pronounced, at the opening of the session in 1772, a Latin oration on the *Vital Principle* in man; which was published in the following year. About the same time appeared his work, entitled, *Nova Doctrina de Functionibus Corporis Humani.* These two works contain a sketch of his peculiar doctrines in physiology; doctrines which he more fully explained in a subsequent book, under the title of *Nouveaux Elémens de la Science de l'Homme,* 8vo, Montpellier, 1778; and of which we shall presently give an account.

In 1774, he was created joint chancellor of the university, with the certainty of succeeding singly to the office on the death of his colleague, which happened in 1786. He afterwards took the degree of doctor in civil law, and was appointed counsellor to the Supreme Court of Aids at Montpellier. In 1780, he was induced to fix his residence in Paris, having been nominated consulting physician to the King, with a brevet of counsellor of state, and a pension of a hundred louis. Honours now crowded upon him; he was admitted free associate of the Academies of Sciences and of Inscriptions, and appoint-

Barthez.

ed first physician to the Duke of Orleans, in the room of Tronchin. His reputation increased in proportion as his merits could be displayed on a wider theatre. He practised as physician at Paris for nearly ten years, and received the most flattering testimonials of public approbation.

This brilliant career was suddenly interrupted by the great political revolution which broke out at this period, and by which the interests of every individual in France, however tranquil his pursuits, or obscure his station, were more or less immediately affected.

It was the occasion of Barthez quitting Paris, and seeking in his native province that tranquillity and repose, which the stormy aspect of the times forbade him to hope for in a more conspicuous station, holding, as he did, opinions so much at variance with the new order of things. Though he had lost the greater part of his fortune, acquired by so much labour, and was deprived of the honours to which he possessed so just a claim, he determined, upon his retiring to Carcassone, that he would practise his profession gratuitously, and devote all his leisure hours to the speculative studies connected with it, which had been the ruling passion of his life. It was in this retreat that he gave to the world his *Nouvelle Méchanique des Mouvemens de l'Homme et des Animaux*, which appeared in 1798, in quarto; and it was at this period, also, that he composed his work on *Gout*, a disease to which his attention had been naturally directed, in consequence of his having frequently suffered under its attacks.

An occasion soon occurred which demanded his services, and he once more emerged from his retirement, and repaired to the head-quarters of the army of the Eastern Pyrenees, where a contagious fever, originating from the accumulation of sick in the military hospitals of Perpignan, was committing great ravages. The progress of this contagion was effectually arrested by the adoption of the measures which he advised.

On the re-establishment of the College of Medicine at Montpellier, Barthez was naturally looked up to as the person best calculated to revive its former fame. But age and infirmity operated to dissuade him from resuming the laborious office of a teacher; and he was accordingly nominated honorary professor. It was in this capacity that he pronounced, in 1801, his *Discours sur le génie d'Hippocrate*, on the solemn inauguration of the bust of the father of medicine in that school. In the following year, he received several marks of favour from the new government under Bonaparte; he was nominated titular physician to the government, and afterwards consulting physician to the Emperor, and member of the Legion of Honour.

His *Traité des Maladies Goutteuses*, in two volumes, octavo, appeared in 1802; and he afterwards occupied himself in preparing for the press a new edition of his *Elémens de la Science de l'Homme*, of which he but just lived to see the publication. His health had been declining for some years before his death; he was subject to attacks of melancholy, which obliged him to desist from pursuits that required intense application, and at length induced him to change the scene altogether, and seek relief amidst the society and amusements of the capital, where he was generally honoured and esteemed. Soon after his removal to Paris, symptoms of the stone manifested themselves, and increased so much in severity, that he was advised to submit to the operation of lithotomy, as affording the only means of arresting a lingering and painful death. But he constantly refused to undergo the pain and risk to which it would have necessarily exposed him, till, after long protracted suffering, during which he had in vain exhausted all the resources of medicine, he was suddenly relieved by a symptomatic spitting of blood; this hæmorrhage, however, was pregnant with new dangers, and, by its continual recurrence, was the immediate occasion of his death, on the 15th of October 1806, in the 72d year of his age. As we have already stated, he had published in the same year a second edition of his *Nouveaux Elémens de la Science de l'Homme*. He bequeathed his books and manuscripts to M. Lordat, who, in consequence, published two volumes of *Consultations de Médecine*, 8vo, Paris, 1810, to which he prefixed a preface of his own. Previous to the appearance of this work, however, a collection of consultations of Barthez, and of some other physicians of Paris, was given to the world by Saint-Ursin; but it appears to have been unauthorized by those to whom he had confided his papers, and contains but few of the consultations which were afterwards published by M. Lordat. Another posthumous work of Barthez, the *Traité du Beau*, preceded by some account of his life, was edited in 1807 by his brother, M. Barthez de Marmorières, who is known as the author of agricultural essays, and projects for improving the maritime coast of Languedoc, together with some translations from the oriental languages; and who has been mistaken, in a recent biographical work, for the subject of the present article.

Barthez has enjoyed a much higher reputation on the Continent than in this country, where, indeed, his writings are but little known. The work which has chiefly contributed to establish his fame, and which contains the developement of his peculiar opinions on physiology, is the *Nouveaux Elémens de la Science de l'Homme*. It is not written, however, with the simplicity and clearness which might have been expected from one who had been in the constant habit of instructing others, and whose lectures were generally admired as possessing those qualities in an eminent degree. He appears to have been early impressed with the futility of all the theories that had been hitherto advanced in explanation of the phenomena presented by living beings, and to have been incited to the bold attempt of raising a new system upon more rational and solid foundations. In the preliminary discourse to the work we have alluded to, he lays down, with great correctness, the fundamental principles of the method of philosophizing in the natural sciences. The common object of these sciences he states to be the research into the causes of natural phenomena, in as far as they can be learned by experience; and shows that we have no direct knowledge of these causes, except as manifested by such of their effects as we perceive. In the infancy of philosophy, numerous causes are assigned to these

Barthez.

apparently diversified effects; during its advancement, and in proportion as the similarity of effects, which had been referred to different causes, is established, the number of these assigned causes becomes more and more circumscribed. Although the real nature of the agents producing those general facts, to which we ultimately arrive by following this method of induction, be absolutely unknown, yet, in reasoning concerning them, we find it convenient to express them by a name, as if they were really known to us; in the same way as in prosecuting an algebraical calculus, we must employ characters to express the unknown, as well as the given quantities. But the distinction should ever be kept in view; and we should err greatly were we to imagine that we could derive any ultimate advantage by the substitution of other symbols, which differed from them only in appearance, or which involved the admission of some hypothetical principle.

Such are the rules by which he professes to be guided in his own investigations; and such the tests by which he examines and passes judgment upon the doctrines of the different sects of Animists, Mechanicians, and Chemists, which had successively prevailed before him in the schools of medicine, and also upon the more recent doctrine of the Solidists, which was then becoming fashionable. In the review which he gives of the opinions of the several leaders of these sects, he displays an accurate acquaintance with the wide circle of medical literature. But, in the prosecution of his plan, he shows, what the example of others has so often proved, that it is easier to overthrow than to build a system; and he evidently violates the strict principles of induction, and of cautious limitation to the province of philosophical inquiry, which he had prescribed, when he engages in the task himself. He sets out with endeavouring to establish a gradation among the causes which operate in producing motion. The simplest of these is the force of impulsion; that of gravitation appears to him less simple; and still less so those of electricity and magnetism. The principles which regulate chemical affinities are more complicated, as well as those which are concerned in the crystallization of bodies. But the forces which produce the phenomena of living vegetables and animals are of a more refined order, and are all referable, according to Barthez, to a single cause, which he denominates the *vital principle*, or *principle of life*. Having established this dogma, he proceeds to discuss a variety of abstruse questions that have been agitated on the subject, such as whether the vital principle has an independent existence, distinct from the organized body which it animates; and whether it be a modification of the soul or rational mind. He gives an elaborate historical sketch of the opinions of philosophers from the earliest times respecting the nature of life, tracing the different sentiments entertained by the followers of Aristotle and Descartes, together with the Stahlians and Boerhaavians, on the one hand; and those of Pythagoras, of Plato, and the sect of Stoics, on the other: the former not acknowledging any principle of life distinct from either matter or mind; and the latter admitting such a principle attached to the living body. A third class of philosophers is noticed, at the head of which he places Bacon, and with which he associates Leibnitz, Cudworth, Van Helmont, and Hoffman, who have recognised the existence of a vital power different from the ordinary physical properties of matter, and at the same time totally distinct from the soul. After expending much useless argument in refutation of the Stahlian doctrine of the identity of the vital with the thinking principles, and devoting a long chapter to the consideration of doubts as to our means of deciding the question, he shows himself strongly inclined to the belief that the principle of life is something which has a separate existence, distinct from any modification, either of matter or of mind. There is little doubt, indeed, that this was his firm persuasion, as he reasons from it in many parts of his work, though he seems averse to declare it, without qualification, while he is discussing these questions. Having thus *personified*, as he very aptly expresses it, this new principle of life, he appeals to it for the solution of every difficulty. It is the master key which unlocks every secret, and renders all the operations of the living animal body perfectly intelligible. Irritability and sensibility are at once the direct effects of this universal agent. All the modifications of these properties, and, in a word, every phenomenon of life, which is not obviously the result of physical laws, are but so many immediate operations of the vital principle. To this fertile source he refers not only the ordinary muscular contractions, but also the slower and less sensible motions which take place in the iris, in the vascular system, and, in general, in those parts in which no muscular structure can be discerned: effects which he attributes to the tonic power of the vital principle. He contends for the existence of another power in the fibres, still derived from the same source; namely, the power of elongation, after they have been contracted; a power which he thinks quite distinct from the other mechanical properties of the fibre, and of which the operation is exemplified in the dilatation of the pupil, the extension of the corpora cavernosa, and of the nipples, and in the diastole of the heart itself. He plumes himself more particularly upon his supposed discovery of a new species of force, distinct from the muscular power, which he terms the *force of fixed situation*, and of which he infers the existence from the circumstance of the tendo Achilles being ruptured, and of the *patella*, and head of the *os calcis* being fractured, on some occasions, by an apparently slight exertion. He avails himself of this principle, also, to explain the phenomena of *tetanus*, and other spasmodic affections.

In a subsequent part of the work, he labours to establish the identity of sensibility and irritability, or, at least, the intimate connection which subsists between them, and the dependence of both upon the immediate and direct operations of the vital principle. He endeavours to prove, that both the sensitive and moving powers are exercised in the circulating fluids of the body; and adduces, in support of this opinion, many of the arguments brought forward by Mr Hunter in proof of the vitality of the blood. On the subject of secretion, implying processes which have been hitherto enveloped in so much darkness,

Barthez.

and of which the explanation has in vain been sought for on mechanical and chemical principles, he is very brief; as it is the peculiar advantage of his theory, like the sword of Alexander, to cut through every knot that bids defiance to ordinary powers of unravelling. Secretion, being inexplicable by any of the hitherto known laws of nature, is, of course, simply the effect of the vital principle. The phenomena of animal heat were in danger of being at once consigned to the same Proteus-like power, which could operate every possible diversity of effects. But chemistry had, in this instance, interposed some plausible theories, which must first be set aside; and Barthez is at great pains to state the reasons of his dissent from the received doctrines on this subject, and of his disbelief in the existence of caloric. He prefers the hypothesis which supposes heat to be a mere quality, excited by motion; and generated accordingly, in living animals, by the intestine motions of their fluids, and the friction of the solids against each other; and the cause of these motions and frictions being unknown, it followed, as a necessary consequence, that they must arise from the operation of the vital principle. Respiration he considers as a cooling or moderating process, and as useful, also, in exciting throughout the system the tonic actions; but all these actions and agitations of the fibres, and these intestine motions of the fluids, are still regulated by the vital principle, which adapts them to variations of climate, and other external circumstances of temperature.

Amidst these vague and unprofitable speculations, his work contains a great store of facts, which are often instructive, though sometimes they expose the credulity of the author. He has collected, for example, a number of curious particulars relative to the operation of different poisons on different animals; but intermingles with these well attested facts, many idle tales respecting the bites of rabid or enraged animals, in which the peculiar manners of the animal were communicated to the human species. Thus, he quotes instances of men barking or attempting to bite in hydrophobia; of some mewing like cats, after having been bitten by these animals; and of others, again, who flapped their arms, and crowed like cocks, after receiving the bite of one of these birds.

A large portion of the work is dedicated to the consideration of Sympathies, which he distinguishes from what he terms Synergies; defining the latter to be the connection, whether simultaneous or successive, of the vital forces of different organs, so as to constitute a function or a disease. He divides sympathies into three classes, according as they occur between organs having no visible relation to each other, those which have similar structures and functions, and those which are united by an intermediate texture, or by receiving the same set of vessels or nerves. His chapter on Temperaments is ably drawn up; and he discusses well the comparative influence of physical and moral causes in modifying the human temperament, and the changes produced by age, and the approach of death. He explains the operation of the more usual causes of death; and enters into a comparison of the mutability of different seasons and climates; and concludes, from several facts and arguments, that the actual cessation of life is, in general, not accompanied by any painful sensation.

Barthez.

The merit of Barthez, as a physiologist, is more conspicuous on subjects which admitted less of his being led astray by his proneness to indulge in abstract speculation, and his predilection for metaphysical refinement. The most favourable specimen of his talents is afforded by his *Nouvelle Méchanique des Mouvemens de l'Homme et des Animaux;* in which, avoiding all discussion as to the cause of muscular motion, he traces the mode in which this force has been applied by nature, according to the principles of mechanism, in effecting the different movements of the animal machine. He examines the relative disposition of the bones and muscles, the structure of the articulations, and the general play and particular motions of the limbs. Borelli (*De Motu Animalium*) had given the first model of such a work; but Barthez has investigated the subject with greater care, and has extended his views to a much wider range of phenomena. He enters minutely into the consideration of a great variety of modes of locomotion, both in man and the inferior animals; for which he has amassed an immense number of facts; forming, altogether, a work which will ever remain a monument of his industry and superior abilities.

In consulting his writings on the practical branches of his profession, we again find ourselves bewildered in a labyrinth of speculations on the proximate causes of disease, and the *modus operandi* of remedies. In his *Treatise on Gout*, he adopts the principles of the humeral pathology, in addition to his own physiological doctrines concerning the force of fixed situation, or principle which retains muscular parts in their appropriate places independently of irritability. He states the proximate cause of this disease to be a specific gouty state of the habit; which he infers from the supposed influence he has observed from specific remedies, and especially *aconite*, in curing it. He defines the gouty state of the blood to consist in "an improper mixture of its component parts, which prevents, in different degrees, the natural formation of its excrementitious humours; so that these humours, being more or less altered, undergo a spontaneous decomposition, which causes the earthy substance to predominate in them." This earthy substance, or, in other words, gouty matter, is deposited upon the extremities, and thus occasions the paroxysm. His practice, on the whole, notwithstanding his adoption of theories now generally exploded, is tolerably judicious; though he shows but little discrimination in the analysis which he gives of the works of practical authors on this disease; and he seems to be strangely deficient in information as to the practice of English physicians. In other respects, his knowledge is accurate and copious; and the history he gives of several of the irregular forms of gout, and also that of sciatica, in which, however, he chiefly follows Cotannius, are deserving of praise.

In the preface to his *Nova Doctrina de Functionibus Naturæ Humanæ*, he has given an excellent ar-

rangement of the general principles of the objects to be kept in view in the medical treatment of diseases. He treats of this subject more at large in his treatise *De Methodo Medendi*, published at Montpellier, in 1777, and also in the preface to his *Traité des Maladies Goutteuses.* He considers all the different methods and indications of cure as capable of being comprehended under three heads, the natural, the analytic, and the empiric. The natural methods have for their object to promote the spontaneous operations of nature tending to restore health, or, as they have been usually termed, the *vires medicatrices naturæ.* The analytic methods are those which proceed upon a previous analysis of the disease into the several simpler diseases of which it consists, or into their ultimate component symptoms, which are isolately and successively combated by means respectively suited to each. These are the more indicated, in proportion as the disease is more complex, and admits of being resolved into a greater number of elements. The empiric plan of treatment is directed to change the whole nature of the disease, by means of which experience has taught us the efficacy in analogous cases. These means are of three kinds; having either a perturbing, an imitative, or a specific operation: the first being such as, by producing effects of a different kind from those of the disease, tend to diminish or entirely suppress the latter (as when the paroxysm of an ague is prevented by the excitement of a strong sudorific or cathartic operation); the second, such as produce effects analogous to those which nature herself employs for the cure of the disease; and the third, those whose salutary operation is known in no other way than as the direct result of experience.

The writings of Barthez appear to have had considerable influence in overthrowing many of the crude and preposterous theories which had prevailed in the schools of medicine; and, however he may have been seduced from the path of genuine philosophy by an excessive disposition to generalize, and an overweening fondness for abstruse speculation, he still deserves the praise of being an original thinker, and of standing pre-eminent among his contemporaries for the courage with which he shook off the trammels of authority, in a university where it had ruled with despotic sway, and where the dogmas of antiquity were held in peculiar reverence. (w.)

BASEDOW (John Bernard), a celebrated German writer, born at Hamburgh, September 11, 1723, was the son of a hair-dresser. Ill treatment made him abandon his father's house. A physician, in a neighbouring village, took him into his service, and shortly after persuaded him to return home to his father. Being placed in one of the lower classes of the college of St John, the severity of his masters rendered him harsh and violent himself. Forced to submit to a slow and rigorous method of study, he contracted a dislike to patience and regularity, which exercised a marked influence over the whole course of his life. Poor but intelligent, he often performed their tasks for his school-fellows, who could afford to pay for it; and they, in return, invited him to their parties of pleasure, which contributed to those habits of irregularity by which his health and reputation often suffered. In 1744, Basedow went to Leipsic to study theology. He gave himself up entirely to the instructions of the professor, Crusius, and the study of philosophy. This, at first, made him sceptical in theology; a more profound examination of the sacred writings, and of all that relates to them, brought him back to the Christian faith; but, in his retirement, he formed his belief after his own ideas, and it was far from orthodox. Having returned to Hamburgh, he lived there without any employment till 1749, when M. de Quaalen, privy-counsellor of Holstein, appointed him preceptor to his son. Basedow now began to apply himself to the subject of education. At first, he would not teach his pupil Latin otherwise than by talking with him in Latin; and he wrote a dissertation on this subject, published at Kiel in 1751, *In usitata et optima honestioris Juventutis erudiendæ Methodus.* In 1753, he was chosen professor of moral philosophy and belles-lettres in the academy of Soroë, in Denmark. Here he published, in 1758, his *Practical Philosophy for all Conditions,* in two volumes (Copenhagen and Leipsic, second edition, in 1777), which contained many good observations on education in general, and on that of girls in particular; but he advanced in it opinions by no means consistent with Lutheran orthodoxy; so that the Count Danneskiold, superintendant of the academy, took his place from him, and removed him to the school of exercises at Altona. Basedow still continued to devote himself to theological studies. In 1764, he published his *Philalethes,* or *New Considerations on the Truths of Religion and Reason, within the Limits of Revelation,* two volumes in 8vo. The magistrates of Altona forbade the reading of this work. He was not allowed any longer permission to print his writings at Hamburgh or Lubeck; the communion was prohibited to him and all his family; and the common people were on the point of stoning him. Basedow, however, who was convinced of the truth of his opinions, displayed prodigious activity in defending them. He wrote his *Methodical Instruction in Religion, and the Morality of Reason,* Altona, 1764; his *Theoretical System of sound Reason,* 1765; his *Essay on Free Dogmatism,* Berlin, 1766; his *Extracts from the Old and New Testament,* and his *Essay in favour of the Truth of Christianity,* in the same year. The last of these works he particularly valued himself upon, because he there founds the evidence of Christianity chiefly on its moral purity. In these, and other works, he, however, maintained several heterodox opinions; as the non-eternity of future punishments,—the inequality of the three Persons of the Trinity,—the insufficiency of the atonement for our sins by the death of Jesus Christ, &c. Constantly persecuted in his theological career, he would have fallen the victim of his incautious zeal, if the Count de Bernstoff, minister of state, and J. A. Cramer, another officer of the court of Copenhagen, had not taken him under their protection. He left off giving lessons, without losing his salary; and, towards the end of 1767, he abandoned theology to devote himself with the same ardour to education, of which he conceived the project of a general reform in Germany. He began by publishing *An Address to the*

Basedow. *Friends of Humanity, and to Persons in Power, on Schools, on Education, and its Influence on public Happiness, with the Plan of an Elementary Treatise on human Knowledge*, Hamburgh, 1768. He proposed the reform of schools, of the common methods of instruction, the establishment of an institute for qualifying teachers; and solicited subscriptions for the printing of his *Elementary work*, where his principles were to be explained at length, and accompanied with plates. For this object, he required 5050 crowns. The subscriptions presently mounted up to 15,000 crowns: the Empress of Russia, Catherine II. sent a thousand crowns, the King of Denmark nine hundred. In 1770 appeared at Altona the first volume of his *Method for Fathers and Mothers of Families, and for the Chiefs of the People*; and six months after, the three first parts of his *Elementary Treatise*, in 8vo, with 54 plates. This work, which was praised in all the journals, was translated into French by Huber, and into Latin by Mangelsdorf; but Schlozer, in the German translation of the *Essay on National Education*, by M. de la Chalotais, accused Basedow of having omitted in his plan various branches of science, and of having had in view only a pecuniary speculation. Basedow, in despair, offered to return the price of his book to those who were not satisfied with it. Only one man, a Swiss, demanded his subscription. Encouraged by the success of the *Treatise*, our author continued to write other works on the same subject, and on the same principles; among others, his *Treatise on Arithmetic*, 1773, and *Elements of pure Mathematics*, 1772. His *Agathocrator*, or *the Education of Teachers to come*, 1771, procured him a medal from the Emperor Joseph II.; and the visits which he made to Brunswick, to Leipsic, Dessau, Berlin, and Halle, to inquire into the state of public instruction, having enabled him to enlarge and correct his ideas, and convinced him that his *Elementary work* contained many erroneous and hasty assertions, he published a new and improved edition of this work in 1774. The same year, he published his *Legacy for Consciences*, or *Manual of natural and revealed Religion*; a work which he composed in order to make known the real state of his religious opinions, and to clear himself from the imputation of wishing to found a new sect. In his travels, he had been well received by the Prince of Anhalt-Dessau, who promised him his protection. From that time, he had resolved to establish an institute for education at Dessau, and to apply his principles himself in forming disciples who might spread them over all Germany. Little calculated, by nature or habit, to succeed in an employment which requires the greatest regularity, patience, and attention, he, however, engaged in this new project with all his accustomed ardour. The name of *Philanthropinon* appeared to him the most expressive of his views; and he published at Leipsic in 1774 a pamphlet, entitled, *The Philanthropinon founded at Dessau*, containing the details of his plan. He immediately set about carrying it into execution; but he had few scholars, and the success by no means answered his hopes. The institution, badly managed, became the theatre of the quarrels between Basedow and the masters who taught in it under his direction. The assistance of the celebrated Campe, a journal which they both composed together under the title of *School Dialogues*, from 1777 to 1779, and a public examination which went off with eclat, gave a transient splendour to the *Philanthropinon*; but in a short time Basedow quarrelled with Campe, made complaints against his Prince, quitted and returned to the care of the institution; and exemplifying in his conduct the effects of coarse manners, and bad temper, was at length drawn into the most scandalous scenes in his disputes with Professor Wolke, his former coadjutor. This institution was finally shut up in 1793. Basedow for some time had given up all thoughts of education; he returned to his old theological inquiries, and residing sometimes at Magdeburgh, sometimes at Halle, sometimes at Leipsic, he took part in the famous controversy excited in Germany by the *Fragments of Wolfenbütel*, an anonymous posthumous work of Reimarus, published by Lessing. Doctor Semler having written a pretended refutation of the *Fragments*, Basedow, without difficulty, exposed the ill intentions of the author, who secretly attacked the cause he affected to defend; and, with his usual vehemence and frankness, called upon Semler to declare himself openly, offering to indemnify him with his fortune, if this public declaration should prove prejudicial to him. Semler made no reply, and Basedow wrote on. He published his work entitled, *Jesus Christ, the Christian World, and the small Number of the Elect*, in 1784; and the year following, returning to the study, which had divided his time and his powers with theology, he gave the public his *New Method of Learning to Read*, which he employed with success in two schools of little girls at Magdeburgh; and in this occupation he passed four hours every day for some time previous to his death, which took place in this city, July 25, 1790. He died with Christian firmness and resignation, and desired that his body might be opened, wishing (to use his own words) to be still useful to his fellow-citizens after his death. In 1797, a monument of marble was erected on the spot where he was buried.

To manners unpolished and abrupt, he joined gross habits; he was fond of wine, of which he drank to excess; in short, with a character in itself unamiable, he seemed, by his conduct, sometimes to take pains to render his services of no use, and his virtues of no account. Nothing can give a better idea of him than what he says of himself: "The sagacious reader will discover by my writings, that I have been especially called to serve the cause of truth and humanity, in following a path hitherto unknown. My opinions have succeeded one another, as has been seen. I have been at different times Lutheran, sceptic, infidel, a friend to natural religion, a convert to Christianity, a Christian with paradoxical sentiments, and more and more heterodox. In me has been seen a thinker tormented within by his own reflections, and a writer tormented from without, because he has been at one time hated, at another misunderstood. Bold and enterprising in my actions, I have always seen, with a faultering heart, the dangers

Basedow.

which threatened me, and from which Providence has saved me in part. I have made little account of domestic happiness, of friendship, or society. I have suffered the penalty. Occupied in curing others, I have neglected the health of my own mind. Esteem is due to the sincerity of my opinions, rather than to my conduct. I desired ardently to make it perfect, but this would have required more perseverance and more attention than the meditation of abstract truths; accordingly, I have oftener been dissatisfied with myself than with others, with whom, however, for the same reason, I have been rarely satisfied. My heart has had little enjoyment of the consolations of religion, because every occasion led me into difficult researches, and thus weakened the force of sentiment. I regard myself as a man and a Christian, such as there are but few in the world, and such as it is not desirable that there should be many." This frankness, without affectation and without pride, induces us to honour the character of a man who has rendered some services to his country and his age. His work *On the Education of Princes destined to the Throne* has been translated into French by Bourjoing. A list of his writings may be seen in Meusel's *Lexicon of German Writers*, from 1750 to 1800, and a farther account of his life in Schlichtegroll's *Necrology* for 1790. Goethe tells an anecdote of going a journey in company with him and Lavater, who fell into a violent dispute about the Trinity. Basedow consoled himself with the hope of getting some beer and a pipe of tobacco at an inn which he saw before them on the road. When they came to it, Goethe made the coachman drive on to the great chagrin of Basedow, to whom he excused himself by saying, that the sign of the inn was *two triangles*, and as he had such an aversion to one triangle (the scholastic emblem of the Trinity), he was afraid the sight of two might overcome him. This conceit, according to Goethe, pacified our anti-trinitarian divine.

Basedow, in his general writings, endeavoured to apply philosophy to practical purposes, and to give a more popular air to his reasonings than had been usual with his countrymen before his time. He held truth to be of little value without practice, and, indeed, he held its essence to depend chiefly on its utility. He considered external or speculative truth to be a very vague and doubtful thing; and that it is principally the consequences of things to the mind itself, that is, a *moral* necessity, which determines it to believe strongly and consistently on any point, so that that is true to each individual which makes the most lasting impression on his mind, and which he feels to be necessary to his happiness. Thus he regarded practical good as the test of speculative truth. He gave great weight to the principle of analogy, and founded the doctrine of a Providence on this principle. He considered common sense as one ingredient in philosophical reasoning, and rejected all systems which appeared to him to exclude it; such as idealism, the doctrine of monads, and a pre-established harmony. His favourite adage in his system of education, was *to follow Nature*. He wished the mind to be led to knowledge, virtue, and religion, by gentle means, instead of those of constraint and terror. Indeed, his principles on this subject are very nearly the same as those of Locke and Rousseau; and he seems to have done little else than to have given currency in Germany to the same reasonings which those philosophers had taught before him in England and France. He insisted on the disuse of the preposterous and unhealthy dresses used by children and their parents, such as stays, swaddling-clothes, tight bandages round the neck, the knees, &c. He recommended exercise and hardy sports as necessary to the health and activity of the body. He proposed to exercise the judgment by teaching a knowledge of things, and not merely to load the memory with words. He preferred the practical sciences to the speculative, the living to the dead languages, modern to ancient history, things which are more near to those which are more remote. In fine, most of his principles were in themselves sound and good, and have in fact exerted their influence on the actual progress of civilization; they were only erroneous from the excess to which he sometimes appears to have carried them; partly from the natural vehemence of his mind, partly from the natural tendency to paradox on the side of new opinions. Paradox, by exciting attention, and enlisting the passions, is perhaps necessary to contend against prejudice; common sense and reason are lost sight of by both parties during the combat; but in the end they prevail, if they have fair play allowed them. Thus, in the present instance, it is now generally admitted, that something besides the classics is necessary to a liberal education; nor is it thought requisite to arrive at this conclusion through the antithesis to the vulgar opinion of his day set up by Basedow, viz. that the classics are of no use at all in a rational system of education. (z.)

Basedow || Basket-making.

BASKET-MAKING. The earlier arts among mankind, in an uncivilized condition, are restricted to operations on materials which undergo slight and imperceptible changes; and implements are fabricated from substances almost in their natural state. The process of interweaving twigs, reeds, or leaves, is seen among the rudest nations of the world, and there is known even an inferior specimen of art among the natives of Van Dieman's Land, consisting of a bunch of rushes tied together at either end, which, spread out in the middle, forms a basket. But the sudden alteration of shape obviously renders this construction less convenient; whence the same and other tribes make a basket of leaves interwoven, and that so skilfully executed, that it retains either milk or water. A bundle of rushes spread out may be compared to the warp of a web, and the application of others across it to the woof, also an early discovery, for basket-making is literally a web of the coarsest materials. By experience these materials are refined and ornamented, and in the most improved stages of manufacture, neat and useful implements and utensils are produced. Scarcely any nation has been entirely ignorant of the art; and our ancestors in this island made baskets which, we learn, were carried to Rome either for use or ornament.

Various applications of Basket-work.

Basket-making, however, has by no means been confined to the fabrication of those simple and useful utensils from which its name is derived. Of old, the shields of soldiers were fashioned of wicker-

Basket-making.

work, either plain or covered with hides, and the like has been witnessed among modern savages. In Britain, the wicker boats of the natives, covered with the skins of animals, attracted the notice of the Romans; and Herodotus mentions boats of this kind on the Tigris and Euphrates. But there was this difference, that the former seem to have been of the ordinary figure of a boat, whereas the latter were round and covered with bitumen. Boats of this shape, about seven feet in diameter, are used at the present day on these rivers; and boats of analogous construction are employed in crossing the rivers of India, which have not a rapid current. At Hurrial, a town on the western side of Hindostan, the river Toombudra is not fordable from June to October; during which interval, round basket-boats are used to transport people, goods, and cattle, to the opposite sides. They are of all sizes, from three to fifteen feet in diameter, but shallow, not being above three feet in depth; and some will carry thirty men. They are of very simple construction: A number of pieces of split bamboo, twenty for example, are laid on the ground, crossing each other near the centre, and there fastened with thongs; the ends of the bamboos are then elevated by several persons, and fixed asunder at due distance by means of stakes, in which position they are bound by other long slips of bamboo. The latter are introduced alternately over and under the pieces first crossed, and tied at the intersections to preserve the shape. This being completed, beginning from the bottom to the centre, the parts above the intended height or depth of the basket-boat are cut off, and it is liberated from the stakes reversed, and covered with half-dressed hides sewed together with thongs. Nothing can be more expeditious or more simple than the fabrication and materials of these vessels, if they merit that name. One may be made by six men in as many hours. Only two substances, almost always accessible, are used,—hides and bamboo. They are navigated either by paddles where the water is deep, or are pushed over a shallow bottom with long poles; and the passengers within are safely transported, being kept dry by planks and pieces of wood at the bottom. The basket-boats on the river Kristna, in the same country, are about twelve feet in diameter, and four feet deep. Whole armies are thus enabled to continue their march, and even heavy artillery has been in the same manner conveyed across rivers. Sometimes the boats are towed by bullocks fastened to them, and goaded on in the proper direction. We may also observe, that in different parts of the world, whole houses, cottages, fences, and gates, are formed of basket or wicker-work. On the Continent, a two horse carriage, called a Holstein waggon, of very considerable size, and fit to carry several persons, is composed solely of basket-work; the same is done in Britain with regard to the bodies of gigs; and an appendage of the stage-coaches is literally designed *the basket*; besides a vast variety of works on a smaller scale.

Materials employed.

In respect to the materials employed, besides those specified as belonging to the ruder nations, there are many which are equally the product of nature and art. Twigs, branches, straw, and whalebone, are all of the number. The natives of some parts of South America make baskets simply of rushes, so closely interwoven as to hold water, and thousands of them are annually sold in the Spanish provinces. The Caffres and Hottentots are alike skilful with the roots of plants. Thus it does not belong to Europeans to rival an uncivilized tribe in the exercise of a simple art. But of all materials, osiers or willows are in most general use.

Osiers for Basket-making.

Osiers, employed for basket-making, are either taken entire, cut from the root, split asunder, or stripped of their bark, according to the work to be produced; but in the latter case, they are previously soaked in water. The stripping is performed by drawing the willows through an iron-edged implement called brakes, which removes the bark, and the willows are then cleaned, so far as necessary, by the manual operation of a sharp knife. Next they are exposed to the sun and air, and afterwards placed in a dry situation. But it is not less necessary to preserve willows with their bark in the same manner, for nothing can be more injurious than the humidity inherent in the plant; and previous to use, they must be soaked some days in water also. The barked or white osier is then divided into bundles or faggots according to size; the larger being reserved to form the strong work in the skeleton of the basket, and the smaller for weaving the bottom and sides. Should the latter be applied to ordinary work, they are taken whole, but for implements of slight and finer texture, each osier is divided into splits and skains; which names denote the different degrees of size to which they are reduced. Splits are osiers cleft into four parts, by means of a particular implement employed for that purpose, consisting of two edge tools placed at right angles, whereby the rod is longitudinally divided down the pith. These are next drawn through an implement resembling the common spoke-shave, keeping the grain of the split next the wood or stock of the shave, while the pith is presented to the edge of the iron, which is set in an oblique direction to the wood: And in order to bring the split into a shape still more regular, it is passed through another implement called an upright, consisting of a flat piece of steel, each end of which is fashioned into a cutting edge, like that of an ordinary chisel. The flat is bent round, so that the two edges approach each other at a greater or less interval by means of regulating screws, and the whole is fixed in a handle. By passing the splits between the two edges, they are reduced to skains, the thickness of which is determined by the interval between the edges of the tool. All the implements required by a basket-maker are few and simple: they consist, besides the preceding, of knives, bodkins and drills for boring, leads for keeping the work steady while in process, and where it is of small dimensions, a heavy piece of iron, called a beater, which is employed to beat the basket close as it is augmented. Thus a basket-maker has this great advantage over many other artificers, that he can establish himself in his profession at the most inconsiderable expence either for tools or materials.

Method of Basket-making.

An ordinary basket is made by preparing the requisite number of osiers, and preserving their length considerably greater than that of the finished work.

Basket-making.

They are ranged in pairs on the floor parallel to each other, at small intervals, in the direction of the longer diameter of the basket; and this may be called the woof, for, as we have said, basket work is literally a web. These parallel rods are then crossed at right angles by two of the largest osiers, with the thick ends towards the workman, who places his foot upon them; and weaving each alternately over and under the parallel pieces first laid down, they are by that means confined in their places. The whole now forms what is technically called the slat or slate, which is the foundation of the basket. Next, the long end of one of the two rods is taken, and wove under and over the pairs of short ends all round the bottom, until the whole be wove in. The same is done with the other rod; and then additional long osiers are also wove in, until the bottom be of sufficient size, and the woof be occupied by them. Thus the bottom, or foundation on which the superstructure is to be raised, is finished; and this latter part is accomplished by sharpening the large ends of as many long and stout osiers as may be necessary to form the ribs or skeleton. These are forced or plaited between the rods of the bottom, from the edge towards the centre, and are turned up in the direction of the sides; then other rods are wove in and out between each of them, until the basket is raised to the intended height, or, more correctly speaking, the depth it is to receive. The edge or brim is finished by turning down the perpendicular ends of the ribs, now protruding and standing up over each other, whereby the whole are firmly and compactly united. A handle is adapted to the work by forcing two or three osiers sharpened at the end, and cut to the requisite length, down the weaving of the sides, close together; and they are pinned fast, about two inches from the brim, in order that the handle, when completed, may be retained in its proper position. The osiers are then either bound or plaited, in such fashion as pleases the taste of the artist.

This is the most simple kind of basket; from which others differ only in finer materials, and nicer execution; but in these there is considerable scope for taste and fancy, and implements are produced of extreme neatness and ingenuity in construction. Some are formed of twigs or straw entire; others of sections, split of various thickness, coloured, plaited, or plain; and baskets of endless variety in size, figure, and texture, are fabricated according to the artist's inclination. The skains are frequently smoked and dyed, either of dull or brilliant colours, and, by intermixing them judiciously, a very good effect is produced.

Utility of this Manufacture to the Blind.

From the simplicity of this manufacture, a great many individuals, independent of professed basket-makers, are occupied in it; and, fortunately, it affords employment to the blind in the several asylums established for their reception. Not that persons suffering privation of sight are incapable of more ingenious and delicate mechanical exercises; but the facility of teaching and acquiring the principles of basket-making being alike obvious, is one of the strongest recommendations in its favour. At Liverpool, where there is an asylum of this description, the art is practised with success; and in the city of Edinburgh, a number of the blind find employment of the same kind, in the asylum established there.

Progress in the Cultivation of Osiers.

The best materials for basket-making have been principally imported into Great Britain from France and Holland; but the duration of the war induced the inhabitants of this country to endeavour to obtain a supply at home. Cultivation of the osier was imperfectly understood in England, and in Scotland it scarcely received any attention whatever; whence, as a suitable encouragement, that patriotic Society, whose notice is specially directed to the improvement of arts and manufactures, some years ago, offered premiums to those cultivators who should raise the greatest quantity, not being less than 6000 plants on an acre.

It became an object with such cultivators to ascertain, not only the quantity that could be obtained, but the quality of the produce, which was of the greater consequence, as many plants, passing under the general name of osiers, and even possessing their external characters, are ill adapted for the work intended. But considerable light has been thrown on the subject by Mr Philipps of Ely, who was early rewarded by a premium on account of the utility of his observations. He remarks that the osier is a species of salix, of which there are many varieties; and these may be comprehended under two classes; the first containing nine or ten species. None, however, excepting one, the grey or brindled osier, is of use. This, in common with the others, has a light coloured leaf, but is distinguished by the bark being streaked with red or blood colour; and it is of late introduction into Britain on the Isle of Ely, where the observer's experiments seem to have been chiefly made. It grows vigorously, is very hardy and tough, and bleaches well. All the others of the same class prefer a wet soil, where they grow quickly and large, and will flourish even in the most barren kind of peat; but they are coarse and spongy, have a thick pith, and are perishable. Nevertheless, they are sometimes used for coarser workmanship, and are profitable to those who live in the vicinity of places where there is a great demand for osiers, and cheap conveyance. During the interruption of continental intercourse, they were much resorted to by basket-makers; but their inferiority has brought the English baskets into disrepute in foreign markets. The second class, according to Mr Philipps, contains four or five different species. One of these, the Welsh willow, is very tough and durable, but not of a favourable colour; there are two varieties, red and white; the former of which is preferred, and forms part of every plantation, from its particular utility in tying up the bundles of willows, after they have been barked or whitened. Their bitterness is such as to be a protection from the depredations of cattle. Besides these, there are the west country Spaniard, the new willow, the French, and red Kent willow. The first has been superseded by others of superior quality, but experience proves that an acre will carry 2000 plants more of them, with greater advantage, than of some in higher repute. But the best of all is esteemed the French willow; especially as being most adapted for smaller and finer work in baskets, fans, hats, and other light articles. It is rather of slow growth,

Basket-making.

but extremely taper, pliant, close grained, tough, and durable. Great quantities of it are always imported from the continent, its culture being more neglected here than that of others; however, it must be distinguished from a species resembling it, which is characterized by the leaves snapping in a manner as brittle as glass, when drawn through the fingers. Plantations of the French willow have been strongly recommended, as forming a useful commodity, and being always in demand. Having attained the requisite maturity, all willows are cut over and made up into bunches in iron hoops, an ell or 40 inches in diameter, for the manufacturers, and are sold, either in this way or in loads; the price being subject to fluctuation, according to scarcity or abundance.

In regard to the cultivation of osiers, very different opinions prevail; originating, it is probable, from too limited experiments, combined with the diversity of soil and climate. Mr Philipps, whose opinions are entitled to attention, conceives, that autumn and not spring is the most proper season for planting willows; the stagnation of the juices, he considers the true criterion whereby to regulate the period, but not on account of the set so much as on account of the trunk; for if the shoot be severed when the sap is in circulation, the parent plant bleeds to death. The osiers which he planted in the first week of October, he found to have struck roots about Christmas, though there was no external sign of vegetation. In prosecuting this subject, Mr Philipps observes, that he made a plantation in autumn, and filled up part of the ground which was vacant in the following month of March with additional sets. The latter were the further advanced in May, but in June the autumn plants had the advantage, and continued growing well, while many of the others died. In summer, he remarks, "when the fibres have been formed before the winter, or when a tendency to form them has been observed by the swelling of the bark, and particularly at the eye, the plant is enabled to charge itself with a sufficient portion of the juices to answer the demand of spring." Therefore, he concludes, that the proper rule is to plant as early in autumn as the shoots may be cut, without injuring the parent stock. The cultivator lays out the ground in beds or burrows 18 feet broad, digging ditches nine feet wide on each side. The upper surface of the ditches, to the depth of 14 inches, is thrown on the beds, and the remainder of what is excavated from them is used for turf or fuel. The beds, now consisting of about two feet and a half thick of solid earth above the surface of the substratum of peat, are planted in the following autumn, and produce good crops.

Soil best suited for Osiers.

Experiments have been made by various cultivators respecting the suitableness of different soils, and after having borne different kinds of grain. Mr Sheriff has related a profitable mode of culture practised by him in Scotland; and also makes some judicious observations on the subject in general. He remarks, that the finest and most valuable twigs can be procured only from land cured of chilling, weeping springs; and if the soil is not of considerable thickness, it must be rendered so by manure. Moderate moisture is favourable to the production of fine twigs, but water constantly stagnant is ruinous. He proposes to make the cuts or shoots from 15 to 17 inches long, and to allow four or five inches to remain above ground, to be cut over by the surface of the soil, when the heads of the stocks shall, in a series of years, have become too bushy. By this operation, the vigour of the plant is renewed in the most decided manner. Mr Sheriff forgets, however, that, in the time he mentions, a much greater protrusion from the earth will have taken place by the simple vegetation of the plant than necessary to leave room for cutting off the head. It is necessary, in his opinion, to trim and dress the stocks from decayed wood, and to retain only as many buds on each as the plant may be expected to bring to perfection in length and strength of shoot. Thus the superabundant stumps of old wood are cut down, the weakest shoots extirpated in November and December, or March and April, and seldom more than two buds should be left on those selected to stand and produce the next summer's growth. He considers the leading errors of those who have attempted the cultivation of osiers to consist in employing improper soil, peat earth, perhaps, or poor bogs; and also in defective preparation of the soil, though suitable in other respects. Failure may, besides, arise from planting bad or useless species of osiers; putting too few cuts in the ground; neglecting their subsequent culture, particularly during the first spring and summer after plantation; allowing the shoots to be cut over after Christmas, and before the middle of March, which may admit of the stocks being much weakened by hard frosts succeeding heavy rains, immediately after the twigs have been cut, and before the wounds from the knife have healed. By pursuing a system analogous to what is here exposed, he calculates the profits of an acre of osiers at about L. 18, 10s.; and he mentions that he contracted to receive a sum between L. 220 and L. 250, for the produce of twelve statute acres and a half. It does not appear, however, that this was an annual crop, and it is rather to be inferred that willows of several years growth formed part of it. Mr Sheriff's experiments and observations were rewarded with the gold medal of the Society for the Encouragement of Arts and Manufactures. Another cultivator, Mr Wade, calculated his profits on fourteen acres, which were planted with 12,000 sets each, at intervals of 26 inches by 10, as amounting to L. 10 *per* acre.

Among the experiments on the quality of soil may be instanced a plantation made in spring, of large cuttings, 18 inches long, thrust so far into the earth as to leave four or five inches protruding. Part of the ground had been in wheat after summer fallow, and part, which was also planted, had been sown with grass seeds. The plants made a more vigorous shoot in spring than at any subsequent period, and but few failed of the whole. Those which succeeded the wheat produced the best osiers, and those which were planted among the grass seeds the worst. Both stood on a strong clay soil. From the difference seen here, it has been concluded, that, as the cleanest ground produced the best crop, summer fallowing would be advantageous. Another example is given,

Basket-making.

where, of 350 sets planted in garden ground, of which the soil was clay, 341 succeeded, producing, in the first year apparently, a bundle 38 inches in circumference, and some of the osiers above 10 feet long. They were planted in the latter end of March, arranged in rows, between which was sown a crop of beans. Both the interval separating the plants and their age are arbitrary, as is also the extent of the plantation, and we must likewise add the quality of the soil, for experiments have not been made on a sufficient scale to determine the fact. The most superficial observer cannot fail to have remarked the comparative slenderness of all plants crowded together, and the superior strength of those apart from each other. The sets of osiers, for several reasons, should be inserted in regular rows: their age does not appear important, and no where is a more vigorous crop produced than from the root of the oldest tree deprived of its trunk. In general, previous preparation of the ground is profitable; and plantations may thence be formed, which are to be annually cut over for baskets and such light utensils; but the shoot is allowed to grow two, or even four years, if strong rods are required for larger and coarser workmanship. The rapidity and certainty with which this plant vegetates, preserves it in a manner under absolute control, and adapts it particularly for a variety of mechanical purposes. Many cultivators recommend deep insertion of the shoot into the ground; but here there is a limitation; for if too deeply inserted, the vegetation will be less vigorous. At the same time, the powerful tendency to vegetation in a willow is rather an exception to ordinary rules, and although the lower part be injured, roots may spring nearer the surface. But it is not to be overlooked, that if a tree be transplanted into too deep a pit, the root, instead of striking out new fibres, remains inactive, and the tree withers and decays; or if seeds be deposited too deep in the earth, no vegetation will ensue; whereas, even those on the surface will put forth a radicle, and establish themselves there. In the former case, they either lose the germinative faculty, or are destroyed; but, if a tree be transplanted into a shallow pit, the root will spread, and the whole exhibit luxuriant vegetation. These are facts which demand greater attention than they usually receive, and the depth at which the shoots of osiers are inserted should be carefully observed. Nevertheless, we must repeat, that it does appear deep insertion is not equally noxious to them as to other plants.

It is commonly understood, that willows flourish no where but with abundance of water. Undoubtedly, adequate humidity is very essential; but this general position is quite erroneous, as experiment and observation daily testify. Willows growing in water have almost invariably a sickly aspect, few strong or healthy scyons spring from them, and their vegetation is never so vigorous as when they are at some distance from it. Every plant has a predilection for a particular place, where the conditions of its aliment and vegetation concur. The willow requires a considerable degree of humidity, though it will also be seen vigorous on drier soils; but the vicinity of water is an essential quality in selecting a suitable spot for a plantation. The purposes to which the plants are to be applied must be considered, and the circumstances of their growth so regulated, that they become suitable and adapted for them. There is little doubt, that, with due notice and consideration, this plant may receive great amelioration by culture.

Basket-making ‖ Bathing.

All plantations must be well fenced against cattle, as the willow, both shoot and leaf, is a favourite kind of food; and as some particular caterpillars infest the plant at certain seasons of the year, stripping it totally bare and injuring its vegetation, care should be taken to remove them as effectually as possible. (s.)

Medical and Physiological Effects of Bathing.

BATHING. In addition to the historical, economical, and physical details respecting the practice of Bathing, which have been inserted in the body of the *Encyclopædia*, we find many investigations in the works of some of the latest authors, relating to its medical and physiological effects, which require to be attentively considered.

A methodical arrangement of these effects, referred to the respective divisions of therapeutic agencies, would be of great use in enabling us to attain a distinct idea of their nature; but such an arrangement is, in fact, a matter of extreme difficulty, for two reasons; *first*, Because the temperature, the continuance, and the impregnation of the bath, are capable of being so varied, as materially to vary the nature of the remedy, without any distinct limit between its different forms; and, *secondly*, Because the classes of medical agents, to which several of these effects belong, are by no means distinctly defined; to say nothing of the additional complexity arising from the division of the effects into immediate and remote, which is often extremely important. The remote effects, however, being of a more general nature, and relating chiefly to the improvement or deterioration of the actions of the whole system, it is only the immediate effects that require to be accurately analyzed and distinguished; and these we must endeavour to reduce to some methodical classification of therapeutic powers.

Baths, as depending on water, have been naturally referred to the class of *diluent* remedies, in which water is comprehended; and they have sometimes even been recommended as *nutrients;* they may also act as *excitants* of cutaneous sensation; as stimulants, or rather *calefacients*, increasing the velocity of the circulation of the blood; as *sudorifics;* as *diuretics;* as "sorbentia" or *sorbefacients;* as refrigerants or *astringents;* as *tonics;* and as *retardants* of the pulse, a capacity in which some would call them relaxants; while they seem in many cases to be useful as antispasmodics, or to relieve certain nervous affections, by something like a *narcotic* or *sedative* power. We might also refer the mechanical effect of ablution, in removing the natural secretions of the skin, to the dietetic *habits* conducive to the preservation of health; but this process, though highly necessary for our comfort, is perhaps less essentially important to health, than has often been imagined; and, in some particular cases, the practice of the very frequent removal of the unctuous and volatile secretions of the skin has even appeared to be injuri-

Bathing.

ous, and to occasion indolent tumours of the absorbent glands belonging to the parts concerned.

If we admit that baths are ever, strictly speaking, either *diluent* or *nutrient*, we must suppose the cutaneous absorbents to be the channels of these actions; and the majority of authors, both ancient and modern, have certainly considered the skin as imbibing, with great facility, not only water, but also any kind of substance capable of being dissolved in it; nor is there any doubt that, under some circumstances, the cutaneous absorbents have been found to possess such a power in a certain degree; but Mr Séguin and Dr Currie have shown that, in common cases, very little or no effect is to be expected from this absorption;* that the strongest medical agents, when dissolved in the water of a bath, exhibited no operation on the system while the skin was entire; and that no perceptible advantage was obtained from a continued immersion in a bath of nutritive fluids, notwithstanding the extreme exhaustion of the system, in a case of completely obstructed deglutition; and they suppose that where weight has been gained during immersion in a bath, the absorption occasioning its increase has been principally performed by the lungs, retaining the moisture, which they receive in abundance with the air inhaled.

The other immediate effects of bathing must depend on the contact of the fluid with the skin, either as simply moistening and softening the cuticle, or as *exciting* a peculiar sensation in the cutaneous nerves, whether of touch only, or of heat or cold, or, in some cases, of slight pain, where the skin has been previously in a state of irritation, especially if the water contains a saline impregnation; or, *lastly*, as altering the state of the circulation by any of these means, especially by the change of temperature; this effect being also often modified by the change of the position of the body, and by the distribution of the pressure or resistance which supports its weight throughout almost the whole surface, instead of its being confined, as usual, to the parts on which we sit or stand. The excitement of the nerves of the skin appears to be salutary in many cutaneous diseases, which are benefited by warm bathing, whether in fresh or in salt water, or in sulfureous or other mineral waters, as at Harrowgate, and at Baden, and Pfeffer and Leuck in Switzerland; the bathers sometimes remaining whole days in the water for weeks together, until a peculiar efflorescence has appeared on the skin, and has again disappeared.† The mud baths in the north of Italy are of a nature somewhat similar, and are said to be of considerable advantage in some paralytic cases. But if we allow the truth of the opinion of Séguin and Currie, we must infer that there are few instances in which the effects of bathing on the system in general can depend much on the impregnation of the water; and we ought perhaps to attribute the acknowledged advantage of sea bathing in a variety of diseases, in great measure, to the mildness and equability of the temperature of the sea. It is true, that persons accidentally wetted with salt water are but little liable to take cold; and this fact has been supposed to indicate some stimulant property in the contents of the fluid; but it may be explained, with greater simplicity, from the slower evaporation of salt water, which causes it to carry off heat much less rapidly than fresh, the cooling process being also retarded by the greater moisture of the sea air.

Bathing.

In order to determine how far any kind of bathing may properly be called a stimulant or *calefacient*, we must consider what are the tests by which we judge of the increased rapidity of the circulation of the blood. The term calefacient is, indeed, somewhat objectionable, as implying, that animal heat depends solely or principally on the motion of the blood, which is not, in the present state of our knowledge, the most probable opinion; and besides this etymological inaccuracy, the definition of the term, as implying an accelerated circulation, involves a considerable difficulty, since we have no means of ascertaining whether increased frequency of pulsation compensates, or not, in any particular instance, for diminished fulness and strength. On the other hand, the operation of almost all medical agents is such as to relieve us from this ambiguity in the application of the definition; for we can scarcely mention any remedy which materially accelerates the pulse, without, at the same time, increasing its strength. There are, indeed, many medicines which are often designated by the vague denomination of stimulants, and which have no effect whatever on the circulation, but either simply *awaken* the nervous energies in general, or *excite* local sensations of heat or pain, and this multiplicity of significations is a sufficient reason for rejecting the term from a correct classification. It happens, however, not unfrequently, that astringent and febrifuge medicines will reduce the frequency of the pulse, and increase its fulness; and it becomes necessary, for an accurate analysis of the operation of remedies which affect the circulation, to distinguish the *accelerants* of the pulse from the *augmentatives* and the *intensitives*, all of which may possibly be independent of the production of an increase of temperature; and this increase may also in some cases be produced, at least in the extremities and the superficial parts, and apparently also in the whole system, without any change in the circulation, by the operation of certain remedies, which might be called *thalptics*, if it were necessary to distinguish them as independent agents: and to these four classes we might add four others of an exactly opposite nature, which might be called *retardants*, *diminutives*, and *remissives* of the pulse, and *psyctics*, or direct refrigerants; and the last four classes would belong to a general division of remedies comprehending those which lessen the force of animal actions; a division which it has not commonly been found necessary to establish, for any practical classification of the materia medica.

Now, it appears that a hot bath, of a temperature exceeding 98°, the usual heat of the human body,

* Currie's *Medical Reports on the Effects of Water*, 8vo. Liverpool, 1798, p. 244.

† *Marcard über die bäder*, 8. Hanov. 1793. *Traduit par Parant*, 8. Par. 1801, p. 40, 41.

Bathing.

will commonly act both as an accelerant and an augmentative of the pulse, but probably not as an intensitive; it may, however, very properly be classed as a calefacient, if such a description of remedies be admitted. Dr Parr* says, that a bath of 100° rendered the pulse fuller and more frequent; but that, after the bath, it was slower than usual; at higher temperatures, the effects were still more marked; and in Marcard's experiments (p. 71) the results were nearly similar. Dr Haygarth observed (*Marcard*, p. 67), that in a bath of 114° the pulse was rendered more frequent, and the arteries were evidently dilated. In Finland, according to Martin (*Marcard*, p. 223), the vapour baths are usually heated to about 120°, and they often increase the frequency of the pulse from 70 in a minute to 110 or 120. Fourcroy mentions a bath of 66° degrees, which must have been of the centigrade scale, making 151° of Fahrenheit, and not 181°, as Marcard supposes (p. 216), which was followed, an hour afterwards, by a fatal apoplexy. Whatever exaggeration there may be in this report, it may still serve to explain to us the excesses which were frequently committed in the use of baths by the Greeks and Romans, and the pernicious effects attributed to them by the ancient physicians. Hippocrates observes (*Aph.* v. 16), that the too frequent employment of hot bathing causes a softness and debility of the muscles, a want of firmness of the nerves, and a dulness of the faculties, with occasional hæmorrhages and faintings, sometimes even terminating in death; and in the *Clouds* of Aristophanes, we have a mock defence of warm bathing deduced from the usual dedication of hot springs to Hercules, which implies a perfect confidence in the opinion of the pernicious tendency of the practice, accompanied, or followed, as it frequently was, by other indulgencies, to which it has too often given occasion. This traditional condemnation of hot bathing has been erroneously transferred by some of the moderns to warm or tepid bathing; and since it has been asserted by authors of high celebrity, that air above 60° will generally occasion a sensation of warmth, it seems to have been inferred that water above 60° must constitute a warm bath, and consequently produce enervating and debilitating effects. The fact is, however, that a bath below 100° is scarcely ever heating in any material degree; and even at 100°, the pulse, though somewhat accelerated, is often not at all augmented in fulness, nor are the subsequent effects materially different from those which usually result from an equal acceleration produced by any kind of moderate exercise. It is observed by Galen in his *Treatise on the Pulse* (*Opp.* Vol. III. p. 3. *Ed. Bas.*), that "baths, when moderately warm, cause the pulse to be full, and strong, and frequent; when excessively hot, small and obscure, but frequent and hard, sometimes, however, after a time, becoming slow, though still feeble." Of this retardation of the pulse in a very hot bath we have no experience in modern times; it is obvious, that what Galen calls moderately warm, we should at present term a hot bath; and probably his excessively hot baths somewhat resembled that which is mentioned by Fourcroy. "Cold baths," he says, "at first make the pulse slow and weak; afterwards, if they disagree, and produce torpor, the pulse remains weak; but if the bath is likely to strengthen the system, producing a salutary glow, then the pulse becomes full and strong, and natural in point of frequency."

It is, however, remarkable, that the cold bath not uncommonly renders the pulse very considerably more frequent at the first immersion; a circumstance which was particularly observed by Athill,† and which, notwithstanding Marcard's doubts, has been since fully confirmed by Dr Stock.‡ This increase of frequency seems principally to depend on the painful sensation of cold occasioned by the first immersion, especially while it is incomplete; it is commonly very transitory, and is succeeded by a retardation, while the fulness of the pulsations is diminished from the first.

The *sudorific* effect of the hot bath seems to be, in great measure, the natural consequence of the acceleration of the circulation, and to be nearly proportional to this acceleration, being also favoured by the softening of the cuticle, and perhaps by the dilatation of the cutaneous exhalants. It is principally recommended in rheumatism, and it is also considered as conducive to the cure of some cutaneous affections; and when this effect is thought particularly desirable, it is usual to take the bath late in the evening, and to promote its operation by going into a warm bed immediately after it.

In considering these and other changes produced in the system by bathing, we must be careful to avoid the very common error of applying inaccurately and indiscriminately the laws of mechanical and physical agents to the effects produced in the animal economy. Some of the latest and best authors on therapeutics have talked of the expansion of the fluids contained in the vessels, in consequence of the elevation of temperature occasioned by the warm bath, and of the contraction of the vessels themselves by the cold bath, as if they were phenomena of the same kind, and simply opposed to each other. The truth is, that the mean temperature of all the fluids in the body is seldom elevated more than a degree or two by the effect of a bath of any kind; and even if the elevation were ten degrees, the expansion of all the circulating fluids would not exceed the bulk of a single additional ounce of blood or of water. The mechanical effect of cold, on the other hand, would immediately tend to lessen the tension of the vessels, by contracting the fluid contained within them more than the vessels themselves; but this effect would be scarcely more sensible than the former, even if we allowed that the general temperature might be depressed 10° or 12°, as it seemed to be in some of Dr Currie's experiments; and the actual contraction,

* *De Balneo, Med. Comm. Ed.* i. 297, or *Marcard by Parant*, p. 66.

‡ *Medical Collections on the Effects of Cold*, 8vo, Lond. 1805, App.

which is really observable in the superficial parts during immersion in the cold bath, can only be referable to the action of living powers, which fall decidedly under the description of involuntary muscularity. Dr Parry's late experiments have very clearly shown the existence of such powers, and exhibited their temporary and local action.* He found that, when the carotid of a ewe was laid bare, its circumference was 525 thousandths of an inch; "but it almost immediately shrunk, through the whole space which was exposed, so as to become in circumference only .470; at the same time, a portion of the artery, before the contracted part, and which had been more recently exposed, was .635; the pulse in the dilated part was very strong and full, that in the contracted part very weak and soft." Dr Parry has chosen to distinguish these effects from those which are observed in other muscular parts by a peculiar denomination; but the distinction appears to be perfectly arbitrary, and Dr Young, whom he quotes as denying the muscular powers of the arteries, on account of the chemical nature of their coats, has expressly asserted their muscularity, in contradiction to the conclusions of Bichât and Berzelius. (*Medical Literature*, 8vo, Lond. 1813, p. 502.) But by whatever term we choose to denote the effect, there is little doubt that an unusual degree of cold has a tendency to produce such a general contraction of the coats of all the superficial capillary arteries; and the diminution of their diameter must necessarily increase that part of the resistance to the blood's motion, which is derived from its friction against the sides of the vessels, and must, therefore, tend materially to lessen its velocity. Again, if the contractions of the heart are at all proportional in magnitude or in frequency to the quantity of blood entering it, and acting as a stimulus to its motions, it is not unnatural to suppose that its pulsations will be rendered feebler by the diminution of that quantity, occasioned by the increase of the resistance, and that the primitive retardation will be redoubled by the operation of this cause. At the same time, however, that the cutaneous vessels are contracted, those of the internal parts must necessarily be enlarged. Hence arises the sensation of oppression on the chest, with the sobbing or panting for breath, which generally occurs at the first immersion in cold water, from the fulness of the vessels of the lungs, and which is increased, in some measure, when the immersion becomes total, by the pressure of the water on the abdomen, and consequently of the contents of the abdomen on the diaphragm. From the same cause arises also the pulsation in the descending aorta, which has been observed to be much more distinguishable after swimming than at other times (*Medical Transactions*, Vol. V.); the internal vessels being distended so as to exhibit the effects of the heart's action more violently, and the heart itself beating with more than usual force in consequence of the exertion, while the contents of the abdomen are compressed, and are enabled, by the presence of the surrounding fluid, to transmit the pulsation very completely to the superficial parts, to which the hand is applied. The *diuretic* effect of a cold bath may be partly explained from a similar distension of the renal vessels, which must be favourable to the secretion of the kidneys; and if the same effect is sometimes produced in a hot bath, when the superficial vessels are rather dilated than contracted, it is in this case much less considerable than in the cold bath, and probably only takes place in consequence of the increased rapidity of the circulation, which affects the whole sanguiferous system.

The glow, which succeeds to the first sensation of cold, may be attributed in great measure to the increased sensibility of the nerves after a partial torpor, rendering them more susceptible of the sensation of heat, which is always relative to the actual temperature of the skin; but it appears, from Dr Currie's experiments, that there is also sometimes a real increase of heat as measured by the thermometer; and it is probable, that the causes concerned in the production of animal heat are called up into a more vigorous exertion, in a strong constitution, whenever they are required for the purposes of life; so that they first supply the superficial parts of the body during the immersion, with as much heat as is necessary to overcome the painful sensation of cold, and afterwards, by a continuation of the same action, occasion an actual elevation of temperature above the natural standard. Dr Currie found, that, during the affusion of a bucket of cold salt water on the heads and whole bodies of two healthy persons, no depression of temperature was observable; but in a minute or two afterwards, although they remained without motion, the mercury rose 2°: in a third person of a feebler constitution, although the temperature remained equally unchanged during the affusion, it sunk, in a minute after, half a degree. These effects seem to be almost entirely independent of any change in the state of the circulation, which must be rather retarded than accelerated, while the generation of heat is increased. It is true, that the heart might be called into more powerful action at the same time that the pulsation at the wrist became feeble, from the permanent contraction of the radial artery; but the action of the heart would still be exhibited by the carotids, undisguised by this modification; and the carotids have not been observed to beat more strongly in the cold bath than at other times, although Dr Currie has remarked, that when "the pulse could hardly be felt at the wrist," "the heart pulsated with great steadiness and due force:" a fact precisely analogous to Dr Parry's interesting experiment on the carotid of the ewe.

Warm baths may be classed with propriety among the most useful *sorbefacient* remedies; but it is not easy to decide, whether they are much more active in promoting absorption than other sudorifics, or than evacuants in general. When the weather deprives a valetudinarian of his accustomed walk, the bath often affords him a valuable substitute, increasing the appetite, and promoting the digestion; but too great an appetite, without muscular exercise, is

* *Experimental Inquiry on the Arterial Pulse*, 8vo, Bath, 1816, p. 41.

sometimes an evil, and this may have been one of the causes of the inconveniences occasioned by an abuse of bathing. A warm bath has often been of advantage in promoting the absorption of dropsical fluids, especially when they are of limited extent, as in cases of partial anasarcous swellings; but the most important sorbefacient effect of bathing is exhibited in the cure of glandular diseases, for which sea water, whether in the form of a warm or a cold bath, has long been considered as a specific remedy; and there is no doubt that a residence by the sea side, with a judicious employment of bathing, and the occasional internal use of sea water, or of some equivalent remedy, has been of the most essential service to many constitutions, which have exhibited these symptoms of general debility and languid absorption; the tonic and sorbefacient powers of the remedy being happily combined, for invigorating and calling into activity the diminished energies of the constitution.

The refrigerant or *astringent* powers, both of warm and of cold bathing, have been abundantly elucidated by the late Dr Currie, who has introduced the remedy into general practice, as a febrifuge, especially in the form of cold or tepid affusion, with the most salutary effects. It is not easy to determine how far the contraction of the superficial vessels by the astringent powers of cold, and how far the *retardation* of the pulse, which may possibly be dependent on that contraction, are concerned in the advantage derived from bathing in fevers; but it is at least obvious that the remedy does not operate simply by the abstraction of heat, since the tepid affusion is often more rapidly successful in abating fever than the cold. We may also collect from the experiments of Marcard, that a bath at about 90° is more efficacious in abating the frequency of the pulse, than at any lower or higher temperature; and these facts appear to afford a very strong argument against the hypothesis, that the principal utility of the cold affusion depends on the sudden shock which is given to the nervous system. Dr Currie has frequently found the pulse reduced by a single cold affusion from 120 or 130 to 80 or 90, and the heat from 104° or 106° to the natural standard. But he very properly limits the employment of the remedy to those cases in which the temperature is considerably elevated, and the arterial system is in strong action, without local inflammation; and where there is less vigour in the system, he often employs the tepid instead of the cold affusion, or even contents himself with moistening the face and the extremities; for instance, in hectic fever, the hands and feet only, which he finds actually hotter than the rest of the body. A late writer on consumption has very justly remarked how much of Dr Currie's reasoning on the effects of cold bathing had been anticipated by Galen, although, for want of a thermometer, he had not been able to employ the remedy in fever with safety. "Bathing," says Dr Young (*On Consumptive Diseases*, 8vo, Lond. 1815, p. 135), "is very strongly recommended in the Method of Healing, and the process is very minutely described: first warm air is employed, next warm water, and then cold water, and lastly, the sweat is wiped off. When we are fatigued or dried up by exercise, the bath restores us to comfort, and defends us from fevers. A strong young man in the country will plunge into cold water at once when heated, and be much refreshed by it. Animals also wash themselves when they are hot, by a natural instinct, as they eat when they are hungry, and seek warmth when they are cold. In fevers, if we had sufficient powers of discrimination, we might probably sometimes derive material advantage from the use of the cold bath, without premising the hot; and some persons have been actually benefited by this remedy. But without a more intimate knowledge of diseases than we possess, we cannot generally venture on the practice; and least of all in hectic fever, where there is not strength enough to bear the shock. A stout young man, having a fever, in warm weather, without visceral inflammation, would bring on a salutary perspiration by bathing in cold water; and if he were in the habit of cold bathing, he might have recourse to it with the more confidence; but, for the hectic, it is unsafe, especially when there is much emaciation: thus, in a hot and dry summer, those who have travelled far, and are become thin and weak, have no need of being cooled, nor would it be safe for them to use the cold bath without first going into the warm. For we seem to be hardened by the cold bath like iron, when heated first; and if we previously warm ourselves by exercise, the effect is the same." Dr Currie's relation of an adventure of his own might almost be supposed to have been intended as a commentary on these remarks of Galen. (*Reports*, p. 120.) "On the 1st of September 1778, two students of medicine at Edinburgh set out on foot on a journey, a considerable part of which lay along one of the rivers of Scotland. They started by sun-rise, and proceeded with alacrity in the cool of the morning. At the end of eight miles, they breakfasted, rested for an hour, and then resumed their journey. The day grew warm as it advanced, and after a march of eight miles more, they arrived heated, but not fatigued, on the banks of the river above mentioned, about eleven in the forenoon. Urged by the fervor of the day, and tempted by the beauty of the stream, they stripped instantly, and threw themselves into the river. The utmost refreshment followed, and when they retired to the neighbouring inn, this was succeeded by a disposition to sleep, which they indulged. In the afternoon they proceeded, and travelling sixteen miles further at a single stretch, arrived at the inn where they were to sleep, a little after sunset. The afternoon had been warm, and they perspired profusely: but the evening was temperate, and rather cool. They had travelled for some miles slowly, and arrived at the end of their journey stiffened and wearied with their exercise. The refreshment which they had experienced in the morning from bathing induced, however, one of them to repeat the experiment, and he went perfectly cool into the same river, expecting to relax his limbs in the water, and afterwards to enjoy profound sleep. The consequences were very different. The Tweed, which was so refreshing in the morning, now felt extremely cold; and he left the water hastily. No genial glow succeeded, but a feverish chill remained for some time, with a small frequent pulse, and flying pains over the

body. Warm liquids and frictions brought on at length considerable heat, and towards morning perspiration and sleep followed. Next day about noon they proceeded on foot, but the traveller who had bathed was extremely feeble; and though they had to perform a journey of a single stage only, as some part of it was difficult and mountainous, he was obliged to take the assistance of a carriage which overtook them on the road. It was several days before he recovered his usual vigour."

The experiments of the same judicious author, published in the *Philosophical Transactions* for 1792, afford some striking illustrations of the effects of severe cold: he employed baths at the temperature of 44° and 40°; the natural pulse of the person subjected to the experiment was about 70 in a minute, and it was generally raised to 85 or more by the preparation for immersion; but in the water it invariably sunk to about 65, becoming firm, regular, and small. The change of temperature, as measured under the tongue, was still more remarkable, and greater than could have been expected either from reasoning or from former observations; for the mercury fell, within a minute or two after immersion, from 98° or 100° to 87° or 88°; it then rose gradually, but not regularly, in a quarter of an hour, to about 96°. Upon a second exposure to the wind, it fell to about 90°, and was in one instance lowered 2° more at the first immersion in a bath of 97½°, in which the natural temperature was by degrees recovered, although not much more rapidly than it had risen during the former immersion in the very cold water; but what raised it by far the most speedily was the application of very hot water to the region of the stomach. When, however, Dr Currie himself went slowly into a bath of 36°, in a light flannel dress, and remained in it for two minutes, no observable alteration was produced in the heat of his body; and this circumstance might almost induce us to suspect that the other subjects of his experiments had incautiously allowed their mouths to be cooled by the inhalation of the cold air.

Dr Marcard's experiments (p. 71) not only confirm the fact of the general retardation and diminution of the pulse by the cold bath; but they show that the retardation commonly extends to all temperatures below that of the human body, becoming, indeed, much more remarkable in the tepid bath than in a bath of the ordinary temperature of the atmosphere, which does not appear to produce the effect with equal uniformity. Thus, in a bath at 60° and at 63°, the pulse was rather accelerated than retarded: in six experiments from 70° to 80° inclusive, taking the mean of all the quantities, in order to obtain a result less liable to accidental errors, and representing all the experiments in a compendious form, the temperature was 75°, and in 20 minutes the pulse was reduced from 78 to 70: in four from 80° to 90°, the mean temperature was 87°, and the pulsations were reduced in 54 minutes from 91 to 75: in three at 90°, the mean reduction in 36 minutes was from 97 to 75: and three experiments above 90° give for a mean temperature 92°, and a reduction from 82 to 70, effected in 35 minutes. Marteau had found a slight reduction of frequency at 93°: but at 96°, according to Dr Parr, there is commonly no observable change. (*Marcard*, p. 63, 66.)

From these experiments Dr Marcard very justly infers, that in a great variety of cases, the warm bath affords the only direct and certain mode of lowering the pulse without inconvenience (p. 88); and we must be contented with the empirical knowledge of this fact, without attempting to explain why a temperature of 90° is more favourable for the retardation of the pulse, than a much lower temperature, at which the thermometrical heat would certainly be more rapidly reduced. Dr Stock has also made several observations on the effect of cold bathing on the pulse; but, in his experiments, the retardation was much less constantly observable than the diminution; a variation which frequently occurs when the temperature is very low.

The salutary effects of cold applications, in some cases of gout, were well known to Hippocrates, and have been more lately extolled by Homberg, Floyer, and Pietschen: Marcard (p. 256) very properly states the objections to their employment, and, notwithstanding all that Dr Kinglake has done to recommend them, they have not been adopted by prudent practitioners, except in very recent cases, and in young and unbroken constitutions. Aretaeus prescribes the affusion of cold water for giddiness and headache, and it has certainly been successful in some obstinate cases of this kind (*Marcard*, p. 255); and has even appeared to be a powerful palliative in some descriptions of mania. In fevers, Dr Currie found its effects more permanent than those of the tepid affusion, although not always so speedy.

We have ample experience of the *tonic* powers of bathing in more than one of its forms; although no more than thirty or forty years ago, the great majority of practitioners in Great Britain were disposed to confine these powers within the limits of the cold, or at most of the tepid bath. But travellers in warmer countries had often informed us of the invigorating effect of a warm bath taken after fatigue; and Bruce, in particular, extolled its comforts and its salubrity, from having used it in Egypt. The opinions of Marcard on the same subject were partly made known through Beddoes: Count Rumford, in his thirteenth Essay, has exhibited, in a popular point of view, the benefits which he himself derived from taking the warm bath habitually in the middle of the day rather than at night; and Dr Alexander Buchan, in his work on sea bathing, has assisted in dissipating the remaining prejudices against its employment as a mild tonic. For feeble or enervated constitutions, and for persons who have suffered from great fatigue, it is decidedly preferable to the cold bath; but as the strength is gradually recovered, it may often increase its efficacy to lower the temperature by degrees. We may begin, for instance, with a warm bath at 96° or 98°, and lower it by degrees to 90° or a little less; and hence the transition to the open sea in the middle of a summer's day will not be too abrupt, the water being often heated to 70° or more on a coast well suited for bathing; and if the constitution appears to acquire strength under the experiment, the hour of bathing may be made

earlier and earlier, until the temperature is no higher than about 60°. The time of remaining in the water may also be modified according to the powers of the constitution; a single immersion being the most easily supported, and a longer continuance in the water, till the sensation of cold has subsided, calling forth the faculty of generating heat into fuller action; observing always not only how the health appears to be affected, but which mode is the most conducive to the pleasure or comfort of the individual, which will often throw some light on the operation of the remedy. In most cases it will be found, that where either warm or cold bathing agrees with the constitution, it is followed by a sense of youth, and vigour, and self complacency, which is equally agreeable and salubrious. We must also make allowances for peculiarities of constitution, which may require a deviation from the temperature usually recommended. Thus, there are some persons who have so singular a sensibility, as to feel a bath of 110° not too warm, and to be absolutely chilled by a bath of 100°: and, in such cases, it is probable that at 105° the pulse would not be materially accelerated. In other instances, the cold bath produces headache and dejection of spirits. This inconvenience is sometimes obviated by proper evacuations, which should also always be premised to bathing, where there is any appearance of visceral disease, or of congestion of any kind. The sea water will answer this purpose sufficiently well, either alone or mixed with warm milk, or with some chamomile flowers infused in it; but it has no material advantage over any other cathartic which may be preferred by the patient. It is also recommended by all authors on cold bathing to plunge in head foremost, and this precaution is highly proper where there is any apprehension of headache, but in other cases it is of little moment. If, after all, the cold bath continues to disagree, it will be generally advisable to exchange it for the warm; and after a time it may be proper to give the cold a second trial.

It is unnecessary to enter into a minute detail of the diseases in which bathing is useful as a tonic. It is, however, particularly indicated in a variety of complaints which are peculiar to females; and to weakly children, especially such as are ricketty and scrofulous, sea bathing is most essentially necessary. On the other hand, cold bathing is almost universally to be avoided where there is any consumptive disease, or any inflammatory affection of any of the internal parts; an exception which is easily understood, from the natural tendency of cold to cause a congestion of blood in the vessels of those parts, in consequence of the contraction of the superficial vessels. The sudorific effect of the warm bath, followed by the refrigerant quality of the tepid, and the tonic powers of the cold, exhibit a succession of remedies nearly analogous to the mode of treatment which is usually found to be most successful in fevers of various kinds; in most of which we begin with sudorific medicines, and proceed to astringents and tonics. Hippocrates, in his book on the use of liquids, observes that gout is one of the diseases in which both hot and cold applications afford effectual relief; and the remark is equally just with respect to some cases of rheumatism; but, more commonly, the best mode of using baths in rheumatism is to begin with a bath raised, during the immersion, to as high a temperature as the patient can bear, so as to act as a powerful sudorific, and to continue the course, when the pain has been relieved, at lower and lower temperatures, ending it with cold bathing in the open sea.

Notwithstanding the acknowledged utility of warm bathing in a variety of circumstances, there may possibly have been some exaggeration in the marvellous opinions which have been sometimes entertained of its utility for the prolongation of life. Galen has indeed mentioned a number of persons who had attained a great age, and who were in the habit of making daily use of the bath, which is enough to prove that such a habit cannot be extremely pernicious; and if we supposed a constitution to retain all its energies, but to have them concealed and obscured for want of proper stimuli, the warm bath might tend to remove the evil; but it is more natural to believe, that the approach of old age has a tendency to weaken the radical powers of the constitution, which cannot afford to be roused into disproportionate exertion; and to apprehend, that the temporary vivacity and activity, superinduced by any foreign agent, whether by warm bathing, or by a removal to a warmer climate, would only tend still more to exhaust the already diminished store of vitality.

The *narcotic* and *sedative*, or *specifically* antispasmodic effects of bathing are most effectually exhibited, in ordinary cases, by the warm or tepid bath, which is often employed for the relief of pain, and for the removal of any irregular or convulsive affection. Possibly also the effect of the warm bath in retarding the pulse may be partly derived from its sedative power as affecting the heart; and if we take this connexion for granted, we may infer from it, that the antispasmodic effect will be most advantageously obtained from a bath at 90°, which has been found to retard the pulse the most effectually. But where there is internal inflammation, it may be desirable to dilate the superficial vessels by a bath somewhat hotter than this, so as to relieve the internal parts from a part of the fluid which distends them, but without increasing the velocity of the circulation by too high a temperature. The cold affusion is also a powerful remedy in many cases of tetanic disease. Hippocrates (*Aph.* v. 21) has remarked, that it often creates a glow which overpowers the convulsive contraction, especially where the subject is young and athletic, the weather hot, and the disease independent of local injury; and the modern experience of Dr Wright and Dr Currie has confirmed and extended the observation. In another passage he tell us (*Aph.* v. 25), that the abundant affusion of cold water generally relieves and removes swellings and pains in the limbs as well as spasms, producing a moderate degree of torpor, which supersedes the pain; but, in fact, the relief of inflammatory affections by cold is rather to be referred to its astringent than to its sedative powers. This is, indeed, a point which has been much discussed by modern theorists; but it must be confessed, that all our

Batties.

theories are of little importance in physic, any further than as they assist us in clearly comprehending and distinctly remembering the facts, which we derive from immediate experience in the treatment of diseases. (V. N.)

BATNEARS, or BATTIES, a people of the north part of Hindostan, inhabiting a country which extends about 200 miles in length, and 100 in breadth, and of which the capital is Batneer, situate, according to some authorities, 170, and according to others, 219 miles west-north-west of Delhi. This country comprehends part of the province of Delhi, Lahore, and Ajmeer.

The Batties present many peculiarities in manners and customs, distinguishing them from the other people of Hindostan. They seem to consist of three different races; the chief are Rajpoot Mahometans; the common people Jauts, who have adopted the same religion; and the cultivators of the soil are called Ryis, a very peaceable and inoffensive class. But in general they are characterized as shepherds; and although principally restricted to the territory whence their name is derived, various tribes of them are to be found in the Punjab; as they are also scattered over the high grounds to the east of the Indus. But great obscurity prevails in every thing regarding them.

The Batties are Mahometans, and highly venerate the memory of a certain saint, Sheik Fereed, who flourished in the fifteenth century; and it is said, that however adverse to their natural disposition, should any one, in invoking his name, claim their protection, it is never withheld. Yet their customs, in other respects, are at variance with those of the Mahometans; and particularly in the females appearing, without any reserve, unveiled in public, and in their associating promiscuously with the men, as in other countries. The wives of the Rajpoot chiefs form an exception; and it is reported among these Rajpoots, that their ancestors migrated some centuries ago from the district of Jesselmere, and after various vicissitudes, settled in the Batneer country. Most of the inhabitants under their rule were originally Jauts, dwelling on the western bank of the river Sutledge, in the twenty-ninth degree of north latitude, and who have not been known long in the portion of the peninsula now occupied by them. Having embraced the Mahometan faith, they were invited by the ancestor of the present Rajah of the Batties to cross the river about a century ago, and settle in his country, where their posterity still reside. The Jauts constitute the lower orders of the people, and are treated with great moderation by their superiors.

The whole territory, extending as above described, is apparently under the dominion of a supreme prince or rajah, whose authority is acknowledged by inferior chiefs or rajahs; for the term rajah, in strictness, applies to none but those invested with a paramount rule. This potentate can bring 20,000 or 30,000 troops into the field, but quite undisciplined, and despising the necessary principle of subordination. His revenue chiefly arises from the plundering of his troops; for their wars are directed more to predatory purposes than to an open contest; and the rajah, instead of repressing the ravages of this immense banditti, willingly participates of the spoils. When strangers observed to him, that the soil and agriculture of his country were sufficient to enable his subjects to enjoy plenty, he replied, that the number of Rajpoots in his service is so considerable compared with the mass of the people, that, should he attempt to restrain the depredations of the latter, the subversion of his own authority might ensue, because it would be interfering with old and established customs. The rajah who made this remark was in every respect a good and humane character.

Batties.

But the people over whom he rules are by no means entitled to the same repute; they are of a cruel, savage, and ferocious disposition; they entertain an utter abhorrence of the usages of civilized life; they are thieves from their earliest origin, and during their predatory incursions into the neighbouring districts, do not scruple, though unresisted, to add murder to robbery. This systematic plundering produces a revenue of above L. 120,000 *per annum* to their princes, at least that is the conjectural amount, for there are no data whereon to form exact calculations.

Many of the Batties appear to be entirely nomadic, changing their residence from place to place, as subsistence fails. Their exports are horses, camels, bullocks, buffaloes, and ghee; and they sell some surplus grain above what is necessary for their own consumption; but their traffic is very inconsiderable; and what they do carry on is with the petty merchants of Behadra, Nohur, and other towns, through the means of the disciples of the Sheik Fereed, their favourite saint. A large portion of the country is unproductive; but along the banks of the river Cuggur, from Batneer to the town of Futtahbad, the soil is uncommonly rich, and well adapted for cultivation. The inundations of this river fertilize its banks, and the subsidence of the waters leaves them to a great distance, prepared for plentiful crops of wheat, rice, and barley, amply rewarding the labours of the husbandman. It is the scarcity of water which occasions the barrenness of the ground; nevertheless, there is more raised than the inhabitants can consume. Their horses are numerous, but it is computed that they lose a fourth of them annually by the sting or bite of a winged insect; for the injured part degenerates into an incurable cancerous sore.

We are unacquainted with any river of note, excepting the Cuggur, which is lost in the sands to the westward of this district. According to the tradition of the natives, its original bed being choked up by immense quantities of earth, forced down from the mountains, its course was altered.

The chief towns of the Batties are Batneer the capital, which lies in a situation almost inaccessible to an enemy, for no water is to be procured within 12 miles, but what supplies the inhabitants; however, it was taken in 1398 by Timour, and more recently by General Thomas. Their other principal towns are Arroah, Futtahbad, Sirsa, and Ramgah, and there are many forts, which, though defenceless against the skill of European troops, are impregnable to the irregular marauders of Hindostan.

Numbers of the Batties have, of late years, emigrated from their native country, to establish themselves in the western parts of the dominions of Oude; and several families of them are to be met with in Rohilcund. They are practised travellers, and well trained to it by the laborious journies undertaken in crossing the great desert to the west of their territories. These expeditions are frequently made by large parties, for the purpose of a predatory incursion on some peaceable country more remote; and they exemplify both skill and determination in attaining their object. Camels previously laden with provisions are dispatched to different stations in the desert, which is about 130 miles in breadth, and deposited there. The most intelligent of the party, about to follow, are selected as guides, and receive the most implicit obedience from their companions during the journey, which closes at the frontier of the hostile country, or rather that to which their hostility is directed. The guides, by long experience, become expert, without compass or land-mark: they seldom fail to conduct the party to the appointed station where the provisions will be found, and thence across the remainder of the desert in safety. But should they accidentally miss the points of rendezvous, and those where their necessities shall be relieved, they are exposed to inevitable destruction, and any of their party heedlessly straying from the rest, become the victims of the accumulated evils of hunger, thirst, and fatigue. The adventurers steer their course by the sun in the day-time, and by the polar star at night; and by similar aids they are enabled to retrace the way they have travelled. Should provisions fail, a bullock is killed, roasted, and partitioned on the spot, and, after a hasty meal, the journey is resumed.

The history of the Batties has attracted the notice of few European authors. They seem to carry on frequent wars with neighbouring states, and are the most formidable enemies that oppose the Rajah of Beykaneer. The latter invaded their territories some years ago, but without success, which is not surprising, considering the comparative smallness of the force which he can bring into the field, and the nature of the country. Temporary advantages were, notwithstanding, obtained over the Batties, and the Beykaneer Rajah erected a fortress in Batinda, which, if not within their territory, is on its immediate confines. This contributed to overawe them for a time, and repressed their incursions into his own domains; as, independent of the garrison, he stationed a large body of cavalry in the fort, whose frequent sallies and captures of cattle annoyed the Batties so much, that they contemplated a total emigration from their own country. But a military adventurer, George Thomas, an Irishman by birth, who, endowed with singular talents and intrepidity, had founded an independent state in the north-west of India for himself, was then at war with the province of Beykaneer. Having reached its frontiers, the Batties solicited his alliance, and, to induce him to espouse their cause the more readily, offered him 40,000 rupees, if he would reduce the obnoxious fort. It appears, that the Beykaneer forces were now masters of Batneer, the capital, whither General Thomas, who had accepted the proposals of the Batties, marched to dislodge them. He found a numerous garrison, and, having brought up his artillery, began to batter the place, preparatory to an assault. This, however, the enemy avoided by capitulation, and was allowed to evacuate the city with the honours of war, while the Batties were put in possession. In further prosecution of the war, several actions ensued, and various fortresses were taken; but it would appear, that one of the Battie chiefs, at variance with General Thomas, commenced hostilities against him, about the period now alluded to; and, in this new warfare with his late allies, his forces were so much reduced by repeated encounters, that, being scarcely able to stand an engagement, he fortified his camps. The Batties, after frequent attacks, withdrew their troops by night, whereon General Thomas took and burnt Futtahbad, and other places, and might have occupied the whole country; but a neighbouring chief, having concluded an alliance with the Batties and sent 1000 cavalry to their aid, General Thomas retreated to Jyjur, a town within his own territory, in order to relieve his people from the fatigues and diseases of the preceding campaign. (s.)

BAUMÉ (Anthony), a druggist in Paris, distinguished by his knowledge of chemistry, and by his practical application of that knowledge, was born at Senlis in 1728. He was the son of an innkeeper, and was put apprentice to the eminent chemist Geoffroy. He had not received a regular school education, a defect which occasioned him many difficulties in prosecuting his scientific researches, which he nevertheless did with much ardour. In 1752, he was admitted a member of the College of Pharmacy. Soon after he was appointed professor of chemistry at that establishment, and in his lectures he displayed the excellent arrangement which is seen in his published works. He carried to a great extent his commercial establishment in Paris for the preparation of drugs for medicine and the arts, such as the acetate of lead, the muriate of tin, mercurial salts, and antimonial mixtures. At the same time, he published papers on the crystallization of salts, on the phenomena of congelation, on those of fermentation, on the combinations and preparations of sulphur, opium, mercury, boracic acid, platina, and Peruvian bark, on the metallic oxides, the acetates of the alkalis, on emetic tartar, on vegetable fecula, and on vegetable extracts. In consequence of these scientific works, Baumé was elected a member of the Academy of Sciences. He wrote a great many articles in the *Dictionnaire des Arts et Métiers*, and had previously published several technological papers, namely on dyeing, on the gilding of clock-work, on a method for extinguishing fires, on the mode of keeping corn, on buildings of plaster, on soap-making, on clay, and on the nature of soils fitted for agriculture. He made numerous experiments along with Macquer, for the purpose of fabricating in France a porcelain equal to the Japanese. He established the first manufactory of sal-ammoniac in France, a substance which before that was obtained from Egypt. He was the first who devised and set on foot a process for bleaching raw silk. Having acquired a competency by the success of these different undertakings, he retired from trade, and devoted his

Baumé || Bavaria.

time to the application of chemistry to the arts. He improved the process for dyeing scarlet at the manufactory of the Gobelins, and he published a cheap process for purifying saltpetre. He bestowed much time in forming an aréometer intended for general use; and published a process for obtaining a mild fecula from the horse-chesnut. By the revolution he lost his fortune, but was not thereby disheartened: this calamity led him to resume his trade. He was chosen a correspondent of the Institute in 1796. He died in 1804, at the age of 76. He was temperate, regular in his habits, and active. Many of his papers are published in the *Mémoires de l'Academie des Sciences.* Of his separate publications, the following may be mentioned here: *Dissertation sur l'Ether,* in 12mo. *Plan d'un cours de Chimie Experimentale,* 1757, in 12mo. *Opuscules de Chimie,* 1798, in 8vo. *Elemens de Pharmacie Theorique et Pratique,* 2 vols. 8vo. *Chimie Experimentale et Raisonnée,* 3 vols. in 8vo, 1773. This last is antiquated, on account of the many improvements which have been made in the science of chemistry since its publication; but his *Elements of Pharmacy* are still useful, as a good dispensary, written with method and clearness: the processes are well described, and the formulæ properly discussed. He did not adopt the Lavoisierian Nomenclature. (Y.)

Recent History.

BAVARIA. This country has undergone several very remarkable changes within the last forty years. The first of these political agitations, in point of time, and the greatest, perhaps, in point of general interest (for, in those days, the European public were not accustomed to the making and unmaking of governments), was the disputed succession in the year 1778. It was occasioned by the extinction of the reigning branch, by the death of the Elector, on 31st December 1777. The right of succession, on the part of the collateral heir (the Palatine of the Rhine), admitted of no doubt; but various fiefs, obtained at successive intervals by Bavaria, were of a nature to be considered in the light of Imperial property, on the failure of the direct line. This, however, was but a small part of the expected change—the House of Austria, having long cast an eager eye on a province which lay so conveniently for annexation, and which had so often, by the influence of France, proved a thorn in its side, was impatient to avail itself of this opportunity of obtaining possession of Bavaria. Little opposition was to be expected from France, the young king (Louis XVI.) being married to a sister of the Emperor Joseph; but a very different conduct was anticipated from Frederick II. This warlike sovereign, though now approaching to his 70th year, came forward in support of the independence of Bavaria with all his characteristic decision; and though unsupported by the heir of the late Elector, found means, by dint of military and diplomatic exertion, to induce the cabinet of Vienna to desist from the chief part of its ambitious pretensions. Had England been so situated as to come forward with the appearance of efficient co-operation, the matter would have been speedily brought to issue; but we were then embroiled with our American colonies, so that the object of the Prussian court was not attained without formidable armaments, and a repetition of manœuvres indicative of hostilities on a large scale. Fortunately, however, the remembrance of the seven years' war, the recollection of the firm stand made by Prussia, and the disposition to resistance evinced by the smaller courts of Germany, had the effect of producing an adjustment without bloodshed. The particulars of this interesting episode in German history, are given at considerable length in a pamphlet lately published, under the title of *Mémoire Historique de la Negociation en* 1778, *au sujet de la Succession de la Bavière.*

Bavaria.

From this time forward, Bavaria remained in profound peace until the French Revolution roused Germany to arms. The Elector, although pacifically disposed, felt it necessary to join a cause embraced by Austria and England, and continued to let his contingent fight along with the Imperialists, until the French found the means of making their way into the interior of the empire. His first departure from the alliance took place in 1796 (August), when Moreau advanced with a powerful army to his capital, and concluded a treaty for a cessation of hostilities, at a moment when the French were expected to invade the Austrian states in three different directions. This time, however, the project of invasion failed, the armies being too much divided, and one of the generals (Jourdan) being ill qualified to meet a moment of emergency. The peace of Campo Formio was concluded next year under circumstances that began to favour the influence of France in Germany, and particularly in Bavaria. This peace lasted hardly two years; and, in the second war, Jourdan advanced once more (March 1799) to experience new defeats at the hand of the Austrians. This army bore the high-sounding name of *Armée de l'Execution de l'Empire,* but its composition bore many marks of the corrupting influence of an interval of peace and bad government. Bavaria remained free from the presence of contending armies for somewhat more than a twelvemonth, until Moreau advanced at the head of a much more powerful and better appointed force. His operations were crowned by the decisive victory of Hohenlinden, and the influence of France over the empire too strongly confirmed by the peace of Luneville.

It is from the date of that treaty (1801) that we are to look for the direct interference of Bonaparte in the affairs of the interior of the empire, where the disunion of Austria and Prussia paralized every wish to assert the independence of the Germanic name. That wish, however, was not strongly felt in Bavaria, where Bonaparte's character was not understood, and where the predominant feeling was a dread of Austria. An alliance was accordingly contracted between Bavaria and France; and when, in the summer of 1805, there remained no farther doubt of the hostile movements of Austria and Russia, Bonaparte thought proper to delay his notice of war until the Imperialists had passed the frontiers of his new ally. The consequence of the disastrous campaign that ensued was the aggrandizement of Bavaria by the cession of various provinces, particularly Tyrol, and the elevation in 1806 of the Elector to the title of King.

Bavaria.

The subsequent resignation of the rank of Emperor of Germany by Francis II. the formation of the Confederation of the Rhine, but, above all, the overthrow of Prussia, rendered the power of France paramount throughout the empire, and enabled her, in 1809, to find, even in a German force, the means of resisting the efforts of Austria. The connection of Bavaria and France, now farther confirmed by the marriage of Bonaparte's step-son to a princess of the reigning family, seemed to rest on an immoveable basis, when the intoxication of success produced at last the memorable march to Moscow, and made the possession of unparalleled power the cause and instrument of its own overthrow.

The Bavarian force engaged in the Russian expedition perished chiefly in the latter part of the retreat, between the Berezina and the Niemen. The horror excited by so melancholy an event, and the hatred inspired by Bonaparte's tyranny for some years back, created a general desire in the Bavarians to make common cause with their countrymen in the north, and vindicate the independence of Germany. The public, however, both there and elsewhere, imagined that the court would not go along with the people; and, after the rupture of the armistice in August 1813, Bavaria stood ostensibly on the side of France. Two months elapsed, before it was discovered that this attitude formed part of the plan concerted with Austria, and discovered to the world only by the sudden march of the Bavarians to interrupt Bonaparte's retreat at Hanau. General Wrede commanded on that occasion with great spirit, and caused a severe loss to the French; but found it impracticable to arrest the progress of a mass which pushed on in close order, regardless of the havock made on its flanks and extremities.

Bavaria now followed, without interruption, the line of policy concerted with Austria, and was not supposed to waver for a moment on the temporary resumption of power by Bonaparte when he landed from Elba. Her unexpected abandonment of him in 1813, is to be attributed to a guarantee from Russia and Austria that she would be maintained in the possession of her actual acquisitions, subject, however, to partial changes, of which the principal was the restitution of Tyrol. That country, proverbially poor, was attached to Austria with all the ardour natural to a retired and simple population. Its relinquishment was, therefore, a slight sacrifice for Bavaria, when compared with the fate that would have awaited her had she ventured, like Saxony, to resist the allies. The proceedings of the Vienna Congress, as well as the subsequent treaties, placed Bavaria on the footing of a power of consequence, confirming the title of the King, granting him a share of the contribution-money paid by France, and stipulating the support of a division of Bavarians, along with the other allies, at the expence of that country.

Military Establishments, Population, and Revenue.

The military establishment of Bavaria has lately been raised to nearly 60,000 men; in peace, it will probably be somewhat below the half. The population, including the late acquisitions, is understood to exceed 3,000,000; the revenue about L.1,500,000 Sterling. Considerable progress has been made during the last half century in redeeming the reproach of ignorance, so long cast on the inhabitants of this, in common with the other southern provinces of Germany; for it must be confessed, that all that we had occasion to lament in regard to the backwardness of education and knowledge in our account of Austria, is applicable to Bavaria. The misfortune of both countries has been a bigoted and ignorant priesthood, who, not content with absorbing in their own hands a very valuable portion of the lands of the country, have all along insisted on the expulsion of the Protestants, and on the observance of the endless holidays and absurd usages which impede the progress of industry among their followers. Hence, a general habit of indolence, and miserable backwardness in agriculture; and, in point of learning, a complete contrast to the northern part of Germany. It would be wrong, however, to carry this unpleasant picture so far as to represent the present generation as worse than their ancestors, or the population as in a state of diminution. On the contrary, Munich hopes ere long to rank among the literary cities of Germany; but ages will be required to bring the population on a level with their northern neighbours.

Bavaria, like Austria and the rest of Germany, has, all along, had the semblance of a representative government, composed of prelates, noblesse, and deputies from the towns. Munich is their place of assemblage; but they have met very seldom for a long time past. That city contains a population of between 40,000 and 50,000 inhabitants, and is one of the handsomest towns in Germany.

As to soil, Bavaria is mountainous and woody towards the south; the ground rising in the direction of the Alps, and containing a number of lakes and marshes, with little that has as yet been brought under tillage. To the northward are plains, extensive and rich, until we reach the Palatinate, which is, in great part, mountainous and woody. The word Palatinate being ambiguous, it may be well to observe that the Palatinate, properly called Bavarian, lies to the north of the Danube, and has Amberg for its capital. But the Rhenish Palatinate belonged likewise, until recent exchanges, to the dominions of this house, the late Elector of Bavaria having been originally a member of the Imperial Diet, in the capacity of Elector Palatine, and having, by his succession to the government of Bavaria, combined the possessions of the two houses. His chief error was, like that of his neighbour, the Emperor Joseph, a desire to introduce improvements without making sufficient allowance for the ignorance of his subjects. He abolished the monastic orders in parts of his dominions, which were by no means ripe for such a change. A great deal has been said about the masonic and other secret societies formed in this country, at the time of the French Revolution, and combining, as was pretended, their efforts with similar societies in Prussia, for the purpose of shaking the established government. These rumours, we are inclined to think, had but slender foundation, there being very little in the condition of Bavaria to afford a promise of success to so strange a project. The present King succeeded to the Electorate in 1799; he was formerly Duke of Deuxponts, and cousin of the preceding Elector. (DD.)

Bayen.

BAYEN (Peter), a celebrated chemist, member of the Institute of France, was born in 1725, at Chalons sur Marne. He showed a great inclination to study, and was sent by his parents to school at Troyes, where he went through a course of classical education with success.

The bent of his disposition was to physical science. He went to Paris in 1749, and became the pupil and friend of an eminent druggist. In this situation, he acquired a complete knowledge of the profession; and before the age of thirty, he was appointed chief apothecary to the French army in Germany, in the seven years' war, a situation which he filled with industry, intelligence, and integrity.

After the conclusion of peace, he returned to Paris. The French government had employed Rouelle to name chemists for the purpose of analyzing the mineral waters which are found in different parts of France, and had allotted funds for this purpose. One of the chemists named was Bayen, and he employed himself ardently in these analyses for several years. His analysis of the waters of Barége and of Bagneres de Luchon are published; and besides the detail of accurate and well-contrived chemical processes, they contain matter interesting to the medical man, to the naturalist, and even to the general reader. He resided at the above-named baths in the Pyrenées, whilst he was employed in analyzing the waters. The project of the French government was not carried farther than the analysis of these waters, so that the public employment of Bayen now ceased.

He returned to Paris, and made the analysis of different minerals which he had collected, chiefly during his residence in the Alpine region of the Pyrenées; amongst them is the marble of Campan, of which there are two varieties, the red and the green. These are brought from that country to Paris, where they make a distinguished figure in ornamental architecture, as may be seen in the columns of the palace of Great Trianon, in the interior of the church of St Sulpice, and in other great buildings. These analyses are published in the *Mémoires presentés à l'Academie par divers Savans*, commonly called *Mémoires des Savans Etrangers*.

He made most accurate experiments on the oxides of mercury, to show that oxidation arises from the absorption of a portion of the atmospheric air, and that the existence of the phlogiston of Stahl could not be proved. Lavoisier was present when the account of these experiments was read, and was employed at the same time in examining the metallic oxides, and it was Lavoisier that brought the subject into a clearer light, and demonstrated the nature of oxygen, and the composition of the atmosphere.

Bayen published an analysis of tin and pewter. In consequence of the writings of some German chemists, fears had arisen amongst the public, that the use of these metals in culinary vessels was pernicious. Bayen showed that these fears were without any ground, if the pewter be of the legal standard, and be not fraudulently mixed with too great a portion of lead.

His mode of analyzing minerals required a long time; he exposed the mineral, without being reduced to powder, to the action of sulphuric acid at the temperature of the atmosphere; after this action had continued for a length of time, he got by lixiviation the sulphates formed by the combination of the acid, with the different component elements of the stone. He did not make use of the trituration of the stone to an impalpable powder, nor its fusion with caustic potash, which facilitate the subsequent action of acids, and which are used with so much advantage in the processes of modern chemists. The account he has published of his analysis will, nevertheless, be instructive to the chemical student, although the excellent and expeditious methods of Klaproth and Vauquelin are those that should be followed in practice.

Bayen || Bazeegurs.

He enjoyed good health till sixty, and died at the age of seventy-six, in the year 1801. He was a man of sound judgment, of strict integrity, and acquainted with several other branches of knowledge besides that which he particularly cultivated. There is a collection of his works, entitled, *Opuscules Chimiques*, 1798, 2 vols. 8vo. (Y.)

BAZEEGURS, a tribe of Indians, inhabiting different parts of the peninsula of Hindostan. The appearance and manners of mankind are so much diversified in the various countries where they dwell, that animated controversies have been excited, whether all have had a common origin; or whether they have sprung from Protoplasts, whose conformation, at the beginning of the world, was dissimilar. Some maintain, that, in consequence of the changes produced by situation, climate, and circumstances, the present generations may possibly exhibit figures and proportions altogether different from those that distinguished their ancestors thousands of years ago; while others hold that no such differences could appear, unless they had actually formed a part of the original conformation of a race. The partisans of either theory have appealed to that uniformity of features and customs known to be continued among tribes, who preserve their own descent pure and unmixed with others, of which the Jews constitute a striking example; and a case something similar, though not equally prominent, is that of the Bazeegurs. This class of people is recognised by several appellations, as Bazeegurs, Panchperee, Kunjura, or Nuts; they follow a mode of life, distinguishing them from the Hindoos, among whom they dwell; they also abstain from intermixing their families with them, and from any intercourse by which they can be united. The name Bazeegur is said to signify a juggler; some etymologists find a probable derivation of conjuror from Kunjura, which might certainly find a corroboration from the similarity of professions. In India, they are dispersed throughout the whole country, partly in wandering tribes, partly adhering to fixed residences, but the greater proportion lead a nomadic life.

History.

The Bazeegurs are divided into seven casts, Charee, Athbhyeea, Bynsa, Purbuttee, Kalkoor, Dorkinee, and Gurgwar; but are the same people, intermarrying as such, and avoiding alliances with other tribes. According to their own traditions, they descend from four brothers, who, finding it difficult to provide for their numerous followers, resolved to separate, and

Bazeegurs. to direct their course respectively to each quarter of the world; in consequence of which, one of them, named Sa, arrived in Bengal from Gazeepour or Allahabad. He took up his abode at Hoogly, and having governed his tribe peaceably during many years, died at Uncourpoor, whither his posterity still repair to offer up their prayers to his manes. Sa left three sons who succeeded each other, and the succession having afterwards regularly passed through several generations, at length devolved to Munbhungee, about fifteen or twenty years ago. At the same time, some of the casts considered a woman called Toota as the chief of the whole; but the power ascribed to the chief seems merely nominal, scarcely amounting to restraint, and not at all to coercion. Munbhungee only resisted the entrance of any of the people, acknowledging the superiority of Toota, to seek a livelihood in the territory occupied by his own sect; and the latter were under the same prohibition with respect to the places frequented by her and her dependents. Besides those who are united into sets or casts, there are individuals who wander about endeavouring to gain a precarious livelihood.

It is not evident, although the Bazeegurs are certainly distinguished by their manners and customs from the natives of Hindostan, that their features discriminate them as a separate race. Some of their women are reputed to be very beautiful, and are thence sought after in those temporary alliances common in the East. The manners of the Panchperee are somewhat different from those of the Bazeegurs; and some of the sects are more civilized than others. It has already been observed, that they are not in the exclusive occupation of any district in particular, but their villages or respective quarters are found in the same places as those of the Hindoos or British settlers. The Panchperee form neat little encampments in the upper provinces; their huts are small and regular, and each is surrounded by a small inclosure or court-yard, generally disposed in such a manner that the whole hamlet, formed of portable matting, obtains a kind of circumvallation by means of them.

Religion. The Bazeegurs, more especially distinguished by that name, are the most civilized of the whole; they are Mahometans in food, apparel, and religion. The Panchperee profess no system of faith in preference, adopting that of any village indifferently, whither their wanderings may guide them. Some traverse the country as Mahometan Fakeers, and live on the ill directed bounty of devotees; and a particular association among them, of bad repute or abject superstition, has been accused of sacrificing human victims. Notwithstanding their ignorance of the established religions, they seem to venerate a female deity, Kali, probably the sanguinary goddess of the Hindoos, and may perhaps in this way seek to purchase her protection. The Bazeegurs are circumcised, and have priests to officiate at their marriages and funerals, but their knowledge of the prophet Mahomet is very imperfect, for they can give little account of him, except that he was a saint. They seem to acknowledge an omnipotent being, and conceive that all nature is animated by one universal spirit, which the soul, as being part of it, will rejoin after death. At the birth of their children, some Bramin, supposed an adept in astrology, is called in to aid them in choosing a propitious name. Bazeegurs.

Among the Panchperee, the marriage ceremony is commenced by the bridegroom repairing to the hut of his elect, and calling aloud for her to be delivered to him. A near relation, guarding the door, resists his entrance, and rudely pushes him away, while he is the object of taunts and jocularity; but when his patience is supposed to have been sufficiently put to the test, the bride is brought out. Both receive an exhortation from the priest to practise mutual kindness, and the bridegroom, marking the bride's face with ochre, declares her his wedded wife, and she, on her part, does the same in return. The little fingers of their hands are now joined, and a scene of merriment, from which the bride alone is exempted, commences. But this consists chiefly in the progress to intoxication, for all these people are addicted to the most immoderate use of spirits; and after copious libations, a cavalcade, formed of the two parties, whose little fingers are again joined, their parents and friends, departs for the hut of the bridegroom. Before the door there are some enigmatical ceremonies performed; the mother of the bridegroom advances with a sieve containing rice, paint, and grass, with which the foreheads of the couple are touched, after being waved around them; and the bride is led into the house, before which there stands a small fresh branch of the mangoe tree in an earthen pot of water. The meaning of these ceremonies is not well understood; but it is to be observed, that the origin of most of the customs of the modern races of mankind, are lost in the darkness of antiquity. Some of the peasantry in Britain have various ceremonies both at marriages and funerals,—such as breaking a cake above the head of the bride, or strewing flowers on the bier of one deceased, which have descended from remote ages, and arose from sources at this day unknown. When these ceremonies are completed among the Bazeegurs, a new scene of mirth is resumed; and towards evening, for the whole day from the breaking of dawn is thus occupied, the bride is conducted to her own hut, when those who are able retire; but the majority, and in general the bridegroom among them, pass the night in a state of insensibility on the neighbouring plain. Manners.

From the earliest period they are accustomed to intoxicating draughts; even infants of five or six months old are supplied with spirits, though their mothers suckle them during five or six years; and it is not uncommon to observe several children of different ages hanging on their mother, and struggling to extract their scanty portion of nourishment, which is gradually diminished by her own insatiable propensities to the same beverage. Many of the sects are very indiscriminate in food; scarce any thing is rejected; dead horses, jackals, and bullocks, are alike acceptable; and it has been suspected that they can even enjoy a repast of human flesh. However, this fact is not authenticated, and if analogical reasoning may be admitted here, we should be inclined to

Bazeegurs. deny it, because there is no proof that any tribe, however savage, is addicted to anthropophagy, if dwelling among a more civilized people.

Occupations. The chief occupation of the Bazeegurs seems to consist in feats of address and agility to amuse the public, in which both males and females are equally skilful. The former are extremely athletic, and the women are taught dancing, which, instead of the graceful motions seen in the north, there consists principally in a display of lascivious gestures. Most, if not all, the men are jugglers, tumblers, and actors, in which they are very adroit. The people of each set, or dramatis personæ, are hired out by a sirdar, or manager of a company, for a definite period, generally one year, after which they are at liberty to join any other party. But no person can establish a set of actors without permission from the Nardar Boutah, a chief of the Bazeegurs, who receives a proportion of the profits, and a tribute or tax from each female, somewhat analogous to what was called milk-money, a revenue levied by the Holy See from licences to prostitutes. On the return of a party from an excursion, this money is paid to the Nardar Boutah, who convenes his people, and they continue feasting until the whole is expended. Should any of the managers be suspected of giving an unfair account of his profits, a court is assembled, where the accused must undergo the ordeal of applying his tongue to a piece of red-hot iron. It thus appears that these tribes have a kind of civil government among themselves; that each of five sets, at Calcutta at least, has a sirdar or ruler, and that the whole are subject to the Nardar Boutah. These sirdars and the chief apparently constitute a court for the trial of infringement of their regulations, which may be followed by punishment. Thus if, on application of the red-hot iron, the suspected manager be burnt, he is declared guilty of a fraud, which is expiated by a fine, and, if it be an aggravated offence, by the additional punishment of having his nose rubbed on the ground. The same penalty is attached to disclosures to strangers of matters which it is the interest of the tribe to conceal. The fine is generally converted to liquor; but should the offender be either unable or unwilling to discharge it immediately, he is banished from all society; or he is universally execrated, and even his wife and children avoid him. He soon finds compliance indispensable, and although the Bazeegurs pique themselves on their honesty, it is conjectured that on such occasions they do not entertain many scruples in acquiring what is so essential to avert the indignation of their fellows. The mulct being paid, is converted to the general behoof, and affords a new opportunity for gratifying the strong propensities implanted in these people for ardent liquors. All differences among this set are the subject of reference either to a *puncheat* or a general assembly; but, before commencing the business, both plaintiff and defendant must provide a quantity of spirits proportioned to the importance of the case. The party non-suited ultimately bears the whole expence, and the assembly is regaled with the beverage produced by the litigants.

Bazeegurs. Some of the Bazeegurs are owners of land, which they entertain a great desire to obtain, but they are never cultivators. They are collected, as already observed, into various associations in different parts of India. The dancing girls, however, have no regular and settled habitations; they dwell merely in temporary huts, erected near the place of their exhibitions. The duration of their lives is supposed to be much abridged by the course of life which they lead, particularly from the violent exercises practised from early youth, and habitual indulgence in intoxicating draughts. Both males and females undergo such a regular progress of debauchery, that few live beyond forty, and many do not attain their thirtieth year. But, from the pursuits of the females being productive to their parents, their marriages are deferred to a later period than is usual in India. There prostitution is free from that odium and contempt which it incurs in Europe, and those females who are considered so unfortunate and depraved by us, are under the special protection of the laws. The female Bazeegurs who are taught singing and dancing only, are under no greater personal restraint than the common dancing girls of Hindostan; but the chastity of those whose particular department is tumbling, is strictly enjoined until their place be supplied by others more youthful. When this substitution comes, they join the companies of dancers alone; and the men, though quite aware of their incontinence, do not scruple to select wives from among them. But, after marriage, a total change of conduct is expected, and it is said that such expectations are commonly realized. Nevertheless, among the Panchperee, the fidelity of those employed in different vocations in the towns becomes suspected, if they have not returned to their homes when the cry of the jackal is heard, and their husbands are by no means disposed to overlook the offence. It does not appear, however, that they have either the power or the inclination of the Hindoos, who sometimes, in such cases, decoy their own daughters to a lonely place for the purpose of perpetrating a barbarous murder on them, as the punishment of their indiscretion. The Bazeegur parents and husbands are content with slighter expiations; but if the paramour be not of their own particular cast, the incontinence of the female is judged a much more grievous fault.

The females now alluded to are those who do not attend the juggling exhibitions of the men, or their feats of activity; they practise physic, cupping, and perform a kind of tattowing on the skin of the Hindoos of their own sex, called Godna. As the men, besides their usual occupations, collect medicinal herbs, and a certain bud, the latter is dried, and the former prepared by their wives as curatives, especially of the complaints of their own sex: thus they find employment in the towns, in such vocations, or by the sale of trinkets, though both afford but a precarious subsistence. Some tribes also exhibit wild beasts to the vulgar, or offer mats fabricated by themselves for sale. Before the establishment of the British government in Bengal, the Bazeegurs were subject to the arbitrary exactions of a tax-gatherer whom they greatly dreaded, and the

apprehension of the renewal of that officer's powers has proved a considerable impediment to investigating their manners and customs.

A general coincidence in the mode of life, the vocations, manners, and language of all the different sects of these people, determine them as belonging to the same race. The distinctions seen among them are too trivial to admit of their being considered of separate and independent origin. They are different from all the other tribes dispersed throughout Hindostan; and have two dialects also peculiar to themselves, the one most probably a jargon, which is spoken only among the public performers; the other, in common use, among the whole. The Bazeegurs are supposed to present many features analogous to the Gipsies scattered over Europe and Asia, where they subsist as a distinct race from all the other inhabitants of the countries frequented by them. Both the Bazeegurs and Gipsies have a chief or king; each has a peculiar language, bearing some reciprocal analogy, and different from that of the people among whom they reside, and this analogy is so decided, that it is difficult to deny, that with both it has had a common origin. In India, and in Europe, they are equally an itinerant race; their pursuits, in so far as modified by the manners of countries distant from each other, are alike; for the discrepancies they exhibit, may reasonably be ascribed to an insensible acquisition of the habits of those near whom the various tribes of mankind dwell. They are equally indifferent as to the quality of the food serving for their subsistence; and equally ignorant of systematic religious principles. All preserve the strictest adherence to their own sect, and sedulously abstain from intermixtures or intermarriages with those of every nation; and where infringements of these rules are seen, they are to be ascribed more to necessity than inclination. Another resemblance, which has probably been lost in the lapse of time, is supposed to consist in the three-stringed viol, introduced into Europe by the jugglers of the thirteenth century, which is exactly similar to the instrument now used in Hindostan. Separate and disjoined, these analogies may not carry conviction of the identity of the European Gipsies with the Indian Bazeegurs, but, on uniting and combining the whole, it does not seem unlikely, that if Asia is their original country, or if they have found their way from Egypt to India, they may also have emigrated farther at a period of remote antiquity, and reached the boundaries of Europe. (s.)

BEATTIE (James, LL.D.), a distinguished moralist and poet, was born on the 25th October 1735, at Laurencekirk, then an obscure hamlet, in the county of Kincardine in Scotland; near which place his father rented a small farm. He received his early education at the common school of the parish; of which it is recorded, that Ruddiman had been teacher in it about forty years before. His acquirements are said to have been interrupted at this time by want of books; a difficulty which has excited commiseration in more instances than that of Beattie, but which is so little able to control natural genius, that it seems almost an incitement to its exertions; as "all impediments in fancy's course are motives to more fancy." He first became acquainted with English versification through Ogilby's translation of Virgil.

By their father's death he had been thrown, while yet of tender age, on the care of his elder brother, David Beattie; who, observing his natural endowments, afforded him, notwithstanding his own limited means, every aid in his power towards a liberal education; and in the year 1749, placed him at Marischal College, Aberdeen; where he soon afterwards obtained a bursary, or exhibition. Here he had the advantage of pursuing his studies under Dr Thomas Blackwell, author of the *Life of Homer*, Dr Gerard, and other eminent men. In addition to his academical course, he began at this time to instruct himself in the Italian language; and appears to have had a strong predilection for Metastasio.

In 1753, he was appointed schoolmaster of Fordun, a small village at the foot of the Grampian mountains, where he likewise performed the duty of precentor, or parish clerk, usually attached to that office in Scotland. Here he indulged the propensities of the youthful poet, and frequently wandered during a whole night in the fields, chewing "the food of sweet and bitter fancy;" and it was from a height in this neighbourhood that his eye first caught a glimpse of the ocean. From the scenery of this secluded spot, he appears to have derived, as might be expected, many of those images which he afterwards transferred into his poetical compositions; and, certainly, no exertion of the inventive powers can furnish representations equal to these immediate copies from nature. Such is that picture in the small poem, which he calls *Retirement*.

> "Thy shades, thy silence, now be mine,
> Thy charms my only theme;
> My haunt the hollow cliff, whose pine
> Waves o'er the gloomy stream;
> Whence the scared owl on pinions gray
> Breaks from the rustling boughs,
> *And down the lone vale sails away*
> *To more profound repose.*"

Such also, among many others in the *Minstrel*, are those beautiful pictures contained in the 20th and 21st stanzas of the first canto.

In this recluse place, Beattie was discovered and noticed by Mr Garden, afterwards Lord Gardenstown, then Sheriff of the county, and by Lord Monboddo. In 1757, he became a candidate for the situation of usher in the Grammar-school of Aberdeen. He was at this time foiled in the competition; but, next year, on occasion of a new vacancy, he was requested to accept the office. Lastly, he was removed, in 1760, to the Professorship of Moral Philosophy and Logic in the Marischal College. Here he passed the remainder of his life, occupied in the zealous discharge of his professional duties, and in literary pursuits. Here, too, he possessed all the advantages of a congenial society, in the company of Dr George Campbell, Dr Reid, Dr Gerard, and other men of genius and learning, who then adorned the university of Aberdeen.

His first publication was a small collection, entitled

Beattie.

Original Poems and Translations, which was printed in 1760 or 1761. Of many of the pieces contained in this little volume he was afterwards ashamed; and not only omitted them in the subsequent selections which he published, but endeavoured, as far as possible, to obliterate all traces and recollection of them. Of these lesser pieces, *The Hermit* is best known; and, though it cannot be considered as a finished composition, is full of pathos and beauty. In *The Battle of the Pigmies and Cranes*, translated from the Latin of Addison, he has displayed a greater command of terse and happy expression than in most of his original pieces.

Mr Beattie was married, in 1767, to Miss Mary Dun, daughter of Dr James Dun, rector of the Grammar-school at Aberdeen. This connection, at first every way auspicious for his happiness, proved, in the sequel, a source of the deepest distress. For, in the course of a few years, Mrs Beattie, whose mother had laboured under a similar malady, showed unequivocal symptoms of mental disorder, which terminated in a state of confirmed insanity.

In the year 1770, Mr Beattie published his *Essay on the Nature and Immutability of Truth, in opposition to Sophistry and Scepticism.* His design was, to "prove the universality and immutability of moral sentiment;" and his motives for the undertaking are sufficiently evident from the title which he has prefixed to the book. He appears to have been particularly encouraged to the prosecution of this task by the opinions of Dr John Gregory and Dr Blacklock. A general outline of the work, which appeared in most of the journals previous to its publication, was prepared by the latter. His original intention, as expressed by himself in one of his letters, was, "first, to have considered the permanency of truth in general;" and, secondly, to have applied the principles which he should have established "to the illustration of certain truths of morality and religion, to which the reasonings of Helvetius, of Mr Hume in his *Essays*, and of some other modern philosophers, seemed unfavourable." Of this plan, the former part only was completed. It is well known that, in the execution of it, the author did not spare the opinions of those whom he considered as the enemies of religious and moral truth; and particularly treated the writings of Mr Hume without reserve or qualification. The friends of the latter took up arms in return, representing the *Essay* as a piece of personal and unprovoked hostility; and, some time after, the opinions which it contained were canvassed in a more public manner, and with much severity, in an *Examination* by Dr Priestley. These attacks, or retaliations, were met by Beattie with the same firmness which he had displayed in the original publication of his sentiments; nor would he ever consent to abate either the plainness or spirit with which he had expressed them.

In proportion to the censure which this publication called forth from a certain number of persons, was its favourable reception with a different class. It was the means of gaining for its author the unsolicited good offices of George Lord Lyttleton, Dr Johnson, Hurd Bishop of Worcester, Percy Bishop of Dromore, and many others. From the great success of the work, a second edition of it was called for in 1771. Mr Beattie visited London in the same year, and again in 1773. On the last of these occasions, he received some flattering marks of public notice and distinction. He had the honour of being admitted to a private and long interview with their Majesties; received, from the University of Oxford, an honorary degree of Doctor of Laws, at the same time with Sir Joshua Reynolds; and was afterwards requested by the latter to sit for his portrait. The reputation of his *Essay*, and still more, perhaps, the motives and general character of the author, likewise procured for him, about this time, a yearly pension of L.200 from the Crown.

Beattie.

In the course of the same year, 1773, he published the first part of his *Minstrel, or the Progress of Genius;* to which he added a second part in 1774. His object, as described by himself, was "to trace the progress of a poetical genius, born in a rude age, from the first dawning of fancy and reason, till that period at which he may be supposed capable of appearing in the world as a Minstrel; that is, as an itinerant poet and musician; a character which, according to the notion of our forefathers, was not only respectable, but sacred." It appears from his letters, that he little anticipated the favourable reception which this poem obtained from the public; a doubt which was probably founded on the want of incident and variety of character, in the composition. Its merit, however, was quickly acknowledged; and by it the author's reputation, as a poet and a man of genius, was raised to its height.

On occasion of a vacancy which occurred soon after in the chair of Natural and Experimental Philosophy at Edinburgh, it was proposed that Dr Beattie should become a candidate; to which step he was strongly urged by some of his friends, particularly Lord Hailes. And, about the same period, he received various offers of preferment in the English church. These plans of promotion, however, he successively declined, considering the situation which he held as best adapted to his abilities, and affording him the greatest opportunities of usefulness. His reluctance to accept a chair in the university of Edinburgh arose partly, indeed, from the remaining effect of those heats which controversial metaphysics had produced. "I am so great a lover of peace," he says in a letter to one of his friends on this occasion, "and so willing to think well of my neighbours, that I do not wish to be connected with one person who dislikes me."

Between the years 1780 and 1793, he published his *Elements of Moral Science*, and various other works, moral and critical, which are well known, and deservedly popular. He enjoyed the acquaintance and friendship of many distinguished characters, in different classes of society. Among his literary correspondents in England were Bishop Porteus, Mrs Montague, Scott the poet of Amwell, and Mr Gray. He was entrusted by the latter, in 1768, with superintending an edition of his poems, printed by Foulis.

During the latter period of his life, Dr Beattie experienced a new train of domestic calamities, which, added to the unfortunate situation of Mrs Beattie,

Beattie.

gradually undermined his health, and impaired his intellectual powers. The first and severest of these trials was the loss of his eldest son, James Hay Beattie, who died in 1790; in whose society he had found one of his greatest enjoyments, and who had already been associated with him in the Professorship of Moral Philosophy, at the early age of 19.* Some years after, his only remaining son, Montague Beattie, likewise died, after a short illness. This event he intimated to one of his friends, by a letter written on the same day, in the terms of calm and unaffected resignation. But his mind had been violently shaken, even before this blow; and, when he looked on the dead body of his son for the last time, he gave way to the scene, and exclaimed, "Now I have done with this world." Its first effect was the loss of memory respecting his deceased son. Yet it was found, that, by the mention of what the latter had suffered during his sickness, his recollection could usually be recalled. He continued to discharge his duty as Professor; but, notwithstanding some returns of a more vigorous intellect and fancy, he did not from this time resume his studies, and seldom answered the letters which he received. He was attacked with palsy in 1799, and afterwards sustained repeated shocks, the last in 1802. He lingered till the 18th of August 1803, when he expired at the age of 68. A particular *Account of his Life and Writings*, by Sir William Forbes of Pitsligo, who had long been his friend and confident, was published in 1806, in which are to be found some interesting selections from his private correspondence.

The character of Dr Beattie is delineated in his writings; of which the most prominent features are purity of sentiment, and warm attachment to the principles of religion and morality. His dispositions were gentle and modest, and he possessed great tenderness of heart. He was laborious in his literary pursuits, yet fond at all times of conversation and society. Towards the latter period of his life he was subject to an irritability of nerves, by which his temper was sensibly affected; and though, to appearance, his bodily frame was robust, he had impaired his strength by excess in study. He possessed considerable talents both for music and drawing.

His abilities as a writer may be said to have already undergone that ultimate test which is to be found in public opinion; and it has ranked him high as a moralist, a critic, and a poet. His *Essay on Truth* became a very popular book, particularly in England, and has gone through many editions. It must be confessed, that this work is not without considerable faults as a philosophical composition. Its leading doctrine has been thus stated by himself: "As we know nothing of the eternal relations of things, *that* to us is, and must be *truth*, which we feel that we must believe; and *that* to us is falsehood which we feel that we must disbelieve. I have shown that all genuine reasoning does ultimately terminate in certain principles which it is impossible to disbelieve, and as impossible to prove; that, therefore, the ultimate standard of truth to us is common sense, or that instinctive conviction into which all true reasoning does resolve itself." It is now generally admitted that, in the illustration of this doctrine, which is conformable in substance to that of Reid, Dr Beattie has fallen into some errors, or at least ambiguities, which the former has been enabled in a greater degree to avoid. What constitutes the chief defect of the *Essay* is a want of that strictness and precision, which a discussion of the metaphysical parts of the subject necessarily requires. He has used the term *common sense* with more latitude, and in a greater variety of significations, than is consistent with exact or conclusive reasoning; and he has stated some propositions too generally, and without the limitations which they seem to require. Notwithstanding this imperfection of the work, when considered strictly as a logical treatise, it is certain that many of the fundamental doctrines delivered in it carry with them an irresistible weight, which subsequent inquiry and discussion have tended, not to diminish, but increase. It may justly be considered as an example, in probable reasoning, of that indirect but conclusive mode of proof, which, in mathematical science, is usually termed *reductio ad absurdum;* a form which has been frequently and successfully employed by Dr Reid, for similar purposes. A reference to the sources of knowledge possessed by mankind in general, and to their common or universal sentiments, is an appeal regarding certain acknowledged facts, as an ingredient and ground-work of science. Nor is it to be supposed that, in these cases, philosophy surrenders her judgment to the popular opinion; but only, that the conclusions of the soundest and the most improved reason are conformable to the dictates of our faculties, as they are exercised by the majority of mankind. The materials of knowledge possessed by the philosopher and the vulgar are the same; it is in the extent of the inferences which are drawn from them, in their combination, and in the uses to which they are applied, that the disproportion is to be found. In their reasoning on mixed subjects, and in the power of remote calculation, men differ infinitely; in their immediate judgments they differ very little.

It is undeniable also, with respect to the style of this work, that Dr Beattie has fallen into an error, by using, on various occasions, a greater keenness of expression than is at all suited to the argumentative parts of his subject. An author may, indeed, be moved by a commendable feeling of indignation, to commence the task of writing, whatever be the subject of discussion. But he who attempts to conduct a train of reasoning, while under the immediate influence even of a just passion, engages in too difficult a matter, and foregoes many advantages. The truth is, that the metaphysical speculations of

* An interesting *Account of his Life and Character*, with a small collection of his compositions, in prose and verse, was printed by Dr Beattie in the year 1800.

Berkeley and Hume had proceeded so far in contradicting the ordinary apprehensions and feelings of mankind, as to prove, in the clearest manner, even to men of science, the impossibility of obtaining certain knowledge, by any exercise of the human intellect, altogether abstracted from the information of matter, and the employment of our other faculties; and those consequences with regard to morality, religion, and the social state, which appeared to flow as a necessary result from the speculative principles, particularly of Mr Hume, roused in a large class, both of the learned and unlearned, a sense of repugnance and opposition proportionally strong. Dr Beattie was among the first who endeavoured to resist the current of these opinions. His book was polemical; and that warmth of language, which he has not studied to repress, must be ascribed to these circumstances, if it cannot be defended by them.

But the objections in question are not applicable to any of his other works. It is impossible here to enter into a farther detail of these various publications. His *Elements of Moral Science*, and his different critical and philological treatises, are compositions of a very pleasing character; and it was chiefly by them that his reputation was established in other countries. Some of his books were early translated into the Dutch and other languages. A French translation of his *Essays on Poetry and Music* was printed at Paris in 1798. But it is chiefly as the author of the *Minstrel* that Beattie is known, and will continue to be admired. This poem, or rather poetical fragment, for the design was not completed, stands fully confirmed in the public favour; and it is sufficient to say, that, in beauty both of sentiment and imagery, it stands in the first class of poetical compositions. It would be difficult perhaps to select, from the body of English verse, any single passage which excels this stanza in the first part:

" O how can'st thou renounce the boundless store
Of charms, which Nature to her votary yields!
The warbling woodland, the resounding shore,
The pomp of groves, the garniture * of fields,
All that the genial ray of morning gilds,
And all that echoes to the song of even,
All that the mountain's sheltering bosom shields,
And all the dread magnificence of heaven;
O how can'st thou renounce, and hope to be forgiven!"

It has been objected to the second part of the *Minstrel*, that it contains too much philosophy. But, though the instruction conveyed in it is frequently addressed to the understanding, it is never abstruse, and the lessons are those of a poet not less than of a moralist. Like the *Castle of Indolence*, it is, in scope and design, a didactic piece. Both commence in the highest strain of descriptive and pathetic poetry; and the subsequent depression of tone in both is a necessary result of this lofty preparation. But the criticism is more just when applied to the work of Thomson than to the *Minstrel*.

Dr Beattie's style is classical, and always perspicuous. He was never weary of retouching what he wrote, the chief secret of good composition, without which, at least, no composition can be rendered complete. He deserves, above all, that which is the greatest praise of an author, that no one can read his works with a candid mind, and rise from the perusal unimproved.

The following is a list of Dr Beattie's writings:—*Poems*, first published in 1760.—*Essay on Truth*, 1771.—*Minstrel*, 1771, 1774.—*Essays*, viz. On Poetry and Music—On Laughter and ludicrous Composition—On Classical Learning, 1776.—*Dissertations*, viz. On Memory and Imagination—On Dreaming—On the Theory of Language—On Fable and Romance—On the Attachments of Kindred—and Illustrations of Sublimity, 1783.—*Evidences of Christianity*, 1786.—*Elements of Moral Science*, 1790, 1793. He likewise published, in 1790, an edition of Mr Addison's papers in the *Tatler*, *Spectator*, *Guardian*, and *Freeholder*, and of his treatise on the *Christian Religion*, with his Life by Tickell, and some original Notes, Edinburgh, 4 vols. 8vo. (EE.)

BEAUMARCHAIS (PIERRE AUGUSTIN CARON DE) appears to have been one of those persons who, from restlessness of disposition and singularity o character, obtain, in their own age, more celebrity than they are entitled to from their merit or talents. He was born at Paris in 1732, and was the son of a clockmaker, who brought him up to his own trade. From his earliest youth, however, he discovered an inclination for literature, together with a remarkable talent for music. His proficiency in that art procured him an introduction to the French court, where he was employed to teach the princesses, daughters of Louis XV. to play on the guitar. At their concerts, which he attended, he became acquainted with the banker Duverney, by whom he was instructed in business, and placed in a situation which was likely to lead to fortune. Beaumarchais first attracted public attention by his drama of *Eugenie*, which was published in 1767; but he was chiefly indebted for the notoriety he obtained, to the various law-suits in which he became involved after the death of his patron Duverney. Having commenced an action against the Count de la Blache, the grand-nephew of Duverney, for payment of a trifling balance of an account which was due to him by his deceased patron, and the suit having been removed from Aix to Paris, M. Goezman, one of the judges of the Parliament Maupeou, which was then very unpopular in the capital, was appointed to report and decide

---

* It is remarkable that this word should have been objected to by Gray, in his *Critique*, communicated to the author previously to the publication of the *Minstrel*. His reluctance to admit a term, which could only be rendered objectionable by being ranked with none but those of the highest and purest class in poetry, would of itself be a sufficient tribute to the diction of this beautiful passage. But Gray does ample justice to the whole stanza: " This," he exclaims, " is true poetry; this is inspiration."

Beaumarchais.

on its merits. Beaumarchais suspecting that he was excluded from the presence of Goezman by the influence of the Count de la Blache, and thus prevented from explaining the merits of his case, bribed certain dependents of the judge in order to be admitted to an interview. The cause, however, was decided against him before he could obtain an audience, and the whole of the bribe not having been returned, a long correspondence took place, by which Goezman was at length so much exasperated, that he instituted a prosecution against Beaumarchais for an attempt to corrupt him in his judicial capacity. Beaumarchais was acquitted of the charge, while Goezman was found liable to him in damages, and was farther convicted of subornation and falsehood in his attempts to substantiate the accusation. The decision of Goezman having been rescinded, and the principal cause remitted to the Parliament of Aix, where it had originally depended, Beaumarchais again became involved with the Count de la Blache, in a litigation which originated in the calumnies and undue influence by which the Count attempted to overpower his adversary. In this dispute, Beaumarchais also prevailed; but the chief advantage which he acquired from these various processes was the astonishing interest and admiration which were universally excited in France by the *Factums* or *Mémoires* which he wrote in his defence; in which the most logical and convincing argument is diversified with the bitterest sarcasm, the keenest raillery, and the relation of incidents as strange and amusing as those which are met with in romance. These able and lively productions, however, procured him many enemies, as they discovered him to be a man of a most resentful and calumnious disposition. He also lost a good deal of the reputation he had acquired, from being involved in a new process, in which he found the advocate Bergasse a more formidable opponent than Goezman or La Blache; and his new *Mémoires* wanted the spirit and gaiety to which his former ones were indebted for their popularity. Though occupied with these processes, and various literary pursuits, Beaumarchais did not neglect the improvement of his fortune. He engaged in various speculations, of which the most profitable was his project of supplying the Americans with arms and ammunition during the war with this country. Having thus gained a considerable fortune, he built a magnificent villa in the Faubourg St Antoine, which he embellished with much taste, and at great expence. He afterwards lost some part of the money he had acquired by an expensive and ill-executed edition of the works of Voltaire; and neither the early support which he gave to the principles of the French Revolution, nor his importation of fire-arms for the use of the French forces, were sufficient to preserve his property from confiscation, or his person from proscription. The sufferings and dangers which he experienced during this period, have been detailed by him in a work entitled, *Mes Six Epoques*, which is written with considerable force and interest. After he had endured every species of accusation and persecution, and had passed some time as an exile from his native country, he returned to France when the storms of the Revolution had subsided into a more settled tyranny, and having recovered possession of his villa in the Faubourg St Antoine, he remained there till his death, which happened suddenly in the year 1799.

The moral character of Beaumarchais seems to have been far from unexceptionable. He was remarkable for extraordinary indiscretion, restlessness, and ambition, an overweening conceit of his own talents, and an undisguised contempt for others. With these defects, it is not wonderful that his conduct should have formed the subject of some absurd calumnies. La Harpe mentions, that these were propagated to such an extent, that it was at one time reported, that he had made away, by poison, with his two wives whom he had successively married for their fortunes—a report, on which Voltaire is said to have remarked, "*ce Beaumarchais n'est point un empoisonneur—il est trop drole.*" Even the journey which he undertook to Spain, in order to vindicate the honour, and secure the happiness of a sister, and which seems to have been the most praiseworthy action of his life, was made the subject of invidious misrepresentations, from which he has vindicated himself in one of his *Mémoires* against La Blache and Goezman.

Besides his *Mémoires*, Beaumarchais is the author of various dramatic productions, which made a great noise, and gained him considerable reputation in Paris at the time they appeared. His *Eugenie*, of which the plot is founded on a story in the *Diable Boiteux*, and his *Deux Amis*, which hinges on the embarrassment and perplexity of a merchant on the verge of insolvency, are serious sentimental comedies, written in imitation of Diderot's *Pere de Famille*. *Eugenie*, which was the most successful of the two, is rather a romance carried on by dialogue, than a drama. It possesses little pathos or interest, and the only emotion felt in its perusal, is a certain degree of curiosity concerning the event of the story. The incidents in *Les Deux Amis* are flat and insipid, and as it is not sustained by the charms of versification, it fails almost entirely of theatrical effect. Beaumarchais obtained more success in his dramatic career, when he quitted the imitation of Diderot, and following the natural gaiety of his own genius, represented the lively and entertaining character of Figaro, in two successive pieces, *Le Barbier de Seville* and *La Folle Journée, ou le Mariage de Figaro*. The first of these comedies merely turns on the assistance which the Count Almaviva receives from Figaro, the *Barbier de Seville*, in his stratagem to carry off Rosine by duping an old guardian, by whom she was strictly watched, and who intended to marry her himself. The *Mariage de Figaro* principally hinges on the scheme devised by the Count Almaviva, of marrying a beautiful attendant of his countess to Figaro, with designs which seem to have been suggested by some scenes in the *Casina* of Plautus. Both pieces are full of lively dialogue, dramatic movement, and ingenious *jeux de theatre*. The author, however, had at first great difficulty in getting the *Mariage*

de Figaro represented; and the curiosity and expectation of the public were excited to the highest pitch, previous to its appearance. It continued to be acted twice a-week for two years, and produced immense profits both to the author and the comedians. To a reader of the present day, the chief interest of the *Mariage de Figaro* arises from the distress experienced by the countess, on finding herself forsaken by her husband, and the engaging, though not very moral, character of the page Cherubin; but in France its popularity might be partly owing to the numerous sarcasms both on the political and judicial administration of the country. This was evidently one of the author's chief objects, as he boasts in his preface, *qu'il a formé son plan de façon à y faire entrer la critique d'une foule d'abus qui desolent la societé.* Beaumarchais has introduced Figaro a third time, in his last drama, *La Mere Coupable;* and it is generally supposed that by this character, in all the three dramas, he intended to represent himself. Figaro, it is true, is originally a barber, and afterwards a *valet;* but he is also a poet, a musician, and great intriguer, while the freedom which he uses with his master gives full scope for the developement of the character. In *La Mere Coupable,* he has also introduced, under the name of Begearss, his old opponent the advocate Bergasse. Indeed, he admits in his preface, *que Begearss n'est pas de son invention et qu'il l'a vu agir.*

Beaumarchais || Beauty.

Most of the plays of Beaumarchais are preceded by prefaces, in which he has vindicated them against objections, and pointed out their beauties; but, as he neither possessed much learning nor taste, his literary pleadings were not so happy as his judicial ones. Indeed, the great secret of Beaumarchais' success was the perceiving and availing himself of the tone and spirit of the times. The vogue in which the *Pere de Famille* then was, secured applause for his *Comedies Larmoyantes.* The unpopularity of a parliament, entrusted with the administration of justice, procured a favourable reception for his *Mémoires;* and the rising clamour against the government of the country, gave additional zest to the sarcasms of the *Mariage de Figaro.* Of consequence, Beaumarchais, during his life, was more celebrated than respectable, and the reputation he enjoyed in his own age was greater than that which he is likely to preserve with posterity. (M.)

BEAUTY.

BEAUTY,—that property in objects by which they are recommended to the power or faculty of TASTE—the reverse of Ugliness—the primary or most general object of love or admiration.

Necessary imperfection of definition, till it be settled whether our sense of Beauty be a simple sensation or otherwise.

These, we confess, are rather explanations of the word than definitions of the thing it signifies; and can be of no value, even as explanations of the word, except only to those who understand, without explanation, all the other words they contain. For, if the curious inquirer should proceed to ask, "And what is the faculty or power of Taste?" we do not see at present what other answer we could give, than that it was that of which Beauty was the object; or by which we were enabled to discover and to relish what was Beautiful. It is material, however, to observe, that if it could be made out, as some have alleged, that our perception of Beauty was a simple sensation, like our perception of colour; and that Taste was an original and distinct sense, like that of seeing or hearing; this would be truly the only definition that could be given, either of the sense or of its object—and all that we could do in investigating the nature of the latter, would be to digest and enumerate the circumstances under which it was found to present itself to its appropriate organ. All that we can say of colour, if we consider it very strictly, is, that it is that property in objects by which they are recommended to the faculty of sight; and the faculty of sight can scarcely be defined in any other way than as that by which we are enabled to discover the existence of colour. When we attempt to proceed farther, and say that Green is the colour of grass, and Red of roses or blood, it is plain that we do not in any respect explain the nature of those colours, but only *give instances* of their occurrence; and that one who had never seen them could learn nothing whatever from these pretended definitions. Complex ideas, on the other hand, and compound emotions, may be always defined, and explained to a certain extent, by enumerating the parts of which they are made up, or resolving them into the elements of which they are composed:—and we may thus acquire, not only a substantial knowledge of their nature, but a practical power in their regulation or production.

State of the question on this point.

It becomes of importance, therefore, in the very outset of this inquiry, to consider whether our sense of Beauty be really a simple sensation, like some of those we have enumerated, or a compound or derivative feeling, the sources or elements of which may be investigated and ascertained. If it be the former, we have then only to refer it to the peculiar sense or faculty of which it is the object; and to determine, by repeated observation, under what circumstances it occurs:—But, if it be the latter, we have to proceed, by a joint process of observation and reflection, to ascertain what are the primary feelings to which it may be referred; and by what peculiar modification of them it is produced and distinguished. We are not quite prepared, as yet, to exhaust the whole of this important discussion, to which we shall be obliged to return in the sequel of our inquiry; but it is necessary, in order to explain and to set forth, in their natural order, the difficulties with which the subject is surrounded, to state here, in a very few words, one or two of the most obvious, and, as we think, decisive objections against the notion of Beauty being a simple sensation, or the object of a separate and peculiar faculty.

Beauty.

The first, and perhaps the most considerable, is the want of agreement as to the presence and existence of Beauty in particular objects, among men whose organization is perfect, and who are plainly possessed of the faculty, whatever it may be, by which Beauty is discerned. Now, no such thing happens, we imagine, or can be conceived to happen, in the case of any other simple sensation, or the exercise of any other distinct faculty. Where one man sees light, all men who have eyes, see light also.—All men allow grass to be green—and sugar to be sweet, and ice to be cold,—and the unavoidable inference from any apparent disagreement in such matters necessarily is, that the party is insane, or entirely destitute of the sense or organ concerned in the perception. With regard to Beauty, however, it is obvious, at first sight, that the case is quite different. One man sees it perpetually, where to another it is quite invisible,—or even where its reverse seems to be conspicuous. Nor is this owing to the insensibility of either of the parties—for the same contrariety exists where both are keenly alive to the influences of the Beauty they respectively discern. A Chinese or African lover would probably see nothing at all attractive in a belle of London or Paris,—and undoubtedly, an *elegans formarum spectator*, from either of these cities, would discover nothing but deformity in the Venus of the Hottentots. A little distance in time produces the same effects as distance in place;—the gardens, the furniture, the dress, which appeared beautiful in the eyes of our grandfathers, are odious and ridiculous in ours. Nay, the difference of rank, education, or employments, give rise to the same diversity of sensation. The little shopkeeper sees a Beauty in his roadside box, and in the staring tile roof, wooden lions, and clipped boxwood, which strike horror into the soul of the student of the picturesque,—while *he* is transported in surveying the fragments of ancient sculpture, which are nothing but ugly masses of mouldering stone, in the judgment of the admirer of neatness. It is needless, however, to multiply instances, since the fact admits of no contradiction. But how can we believe, that Beauty is the object of a peculiar sense or faculty, when persons undoubtedly possessed of the faculty, and even in an eminent degree, can discover nothing of it in objects where it is distinctly felt and perceived by others with the same use of the faculty?

[...]st reason [ag]ainst the [no]tion of [Be]auty be[in]g a peculiar quality, [an]d the ob[jec]t of a [dis]tinct [se]nse or [fa]culty,—[tha]t those [wh]o have [th]e Faculty not recognise this [qu]ality in [th]e same [ob]jects.

This one consideration, we confess, appears to us conclusive against the supposition of Beauty being a real property of objects, addressing itself to the power of Taste as a separate sense or faculty,—and seems to point irresistibly to the conclusion, that our sense of it is the result of other more elementary feelings, into which it may be analyzed or resolved. A second objection, however, if possible of still greater force, is suggested, by considering the prodigious and almost infinite variety of things to which this property of Beauty is ascribed, and the impossibility of imagining any one inherent quality which can belong to them all, and yet, at the same time, possess so much unity as to be the peculiar object of a separate sense or faculty. All simple qualities that are perceived in any one object, are immediately recognised to be *the same*, when they are again perceived in another; and the objects in which they are thus perceived, are at once felt so far to resemble each other, and to partake of the same nature. Thus snow is seen to be white, and chalk is seen to be white; but this is no sooner seen, than the two substances, however unlike in other respects, are felt at once to have this quality in common, and to resemble each other in all that relates to the quality of colour, and the sense of seeing. Now, is this felt, or could it even be intelligibly asserted, with regard to the quality of Beauty? Take even a limited and specific sort of Beauty,—for instance the Beauty of Form. The form of a fine tree is beautiful—and the form of a fine woman,—and the form of a column, and a vase, and a chandelier. Yet how can it be said that the form of a woman has anything in common with that of a tree or a temple? or to which of the senses by which forms are distinguished, does it appear they have any resemblance or affinity?

[Se]cond rea[son]—the [inf]inite variety of ob[jec]ts to [wh]ich the [qu]ality of [Be]auty [mu]st be [hel]d to be[lon]g.

The matter, however, becomes still more inextricable when we recollect that Beauty does not belong merely to forms or colours, but to sounds, and perhaps to the objects of other senses; nay, that in all languages and in all nations, it is not supposed to reside exclusively in material objects, but to belong also to sentiments and ideas, and intellectual and moral existences. Not only is a tree Beautiful, as well as a palace or a waterfall; but a poem is Beautiful, and a theorem in mathematics, and a contrivance in mechanics. But if things intellectual and totally segregated from matter may thus possess Beauty, how can it possibly be a quality of material objects? Or what sense or faculty can that be, whose proper office it is to intimate to us the existence of some property which is common to a flower and a demonstration, a valley and an eloquent discourse?

Suggestion that their *Agreeableness* may be their common quality

The only answer which occurs to this, is plainly enough a bad one; but the statement of it, and of its insufficiency, will serve better, perhaps, than anything else, to develope the actual difficulties of the subject, and the true state of the question with regard to them. It may be said, then, in answer to the questions we have suggested above, that all these objects, however various and dissimilar, agree at least in being Agreeable, and that this *Agreeableness*, which is the only quality they possess in common, may probably be the Beauty which is ascribed to them all. Now, to those who are accustomed to such discussions, it would be quite enough to reply, that though the Agreeableness of such objects depend plainly enough upon their Beauty, it by no means follows, but quite the contrary, that their Beauty depends upon their Agreeableness; the latter being the more comprehensive or generic term, under which Beauty must rank as one of the species. Its nature, therefore, is no more explained, nor is less absurdity substantially committed, by saying that things are Beautiful, because they are Agreeable, than if we were to give the same explanation of the sweetness of sugar; for no one, we suppose, will dispute, that though it be very true that sugar is agreeable because it is sweet, it would be manifestly preposterous to say that it was sweet because it was agreeable. For the bene-

refuted, by general Considerations,

Beauty.

fit, however, of those who wish or require to be more regularly initiated in these mysteries, we beg leave to add a few observations.

and more particularly.

In the first place, then, it seems evident, that Agreeableness, in general, cannot be the same with Beauty, because there are very many things in the highest degree Agreeable, that can in no sense be called Beautiful. Moderate heat, and savoury food, and rest, and exercise, are Agreeable to the body; but none of these can be called Beautiful; and among objects of a higher class, the love and esteem of others, and fame, and a good conscience, and health, and riches, and wisdom, are all eminently Agreeable; but not at all Beautiful, according to any intelligible use of the word. It is plainly quite absurd, therefore, to say that Beauty consists in Agreeableness, without specifying in consequence of what it is agreeable,—or to hold that anything whatever is taught as to its nature, by merely classing it among our pleasurable emotions.

In the second place, however, we may remark, that among all the objects that are Agreeable, whether they are also Beautiful or not, scarcely any two are Agreeable on account of the same qualities, or even suggest their agreeableness to the same faculty or organ. Most certainly there is no resemblance or affinity whatever between the qualities which make a peach agreeable to the palate, and a beautiful statue to the eye; which soothe us in an easy chair by the fire, or delight us in a philosophical discovery. The truth is, that Agreeableness is not properly a quality of any object whatsoever, but the effect or result of certain qualities, the nature of which we can generally define pretty exactly, or of which we know at least with certainty that they manifest themselves respectively to some one particular sense or faculty, and to no other; and consequently it would be just as obviously ridiculous to suppose a faculty or organ, whose office it was to perceive Agreeableness, as to suppose that Agreeableness was a distinct quality that could thus be perceived.

The class of agreeable objects, thanks to the bounty of Providence, is exceedingly large. Certain things are agreeable to the palate, and others to the smell and to the touch. Some again are agreeable to our faculty of imagination, or to our understanding, or to our moral feelings; and none of all these we call Beautiful. But there are others which we do call Beautiful; and those we say are agreeable to our faculty of Taste;—but when we come to ask what is the faculty of Taste, and what are the qualities which recommend them to that faculty?—we find ourselves just where we were at the beginning of the discussion, and embarrassed with all the difficulties arising from the prodigious diversity of objects which seem to possess these qualities.

We know pretty well what is the faculty of seeing or hearing; or, at least, we know that what is agreeable to one of those faculties, has no effect whatever on the other. We know that bright colours afford no delight to the ear, nor sweet tones to the eye; and are therefore perfectly assured that the qualities which make the visible objects agreeable, cannot be the same with those which give pleasure to the ear. But it is by the eye and by the ear that all material Beauty is perceived; and yet the Beauty which discloses itself to these two separate senses, and plainly depends upon qualities which have no sort of affinity, is supposed to be one distinct quality, and to be perceived by a peculiar sense or faculty! The perplexity becomes still greater when we think of the Beauty of poems or theorems, and endeavour to imagine what qualities they can possess in common with the agreeable modifications of light or of sound.

Beauty.

In what the Difficulty of the Subject truly consists.

It is in these considerations undoubtedly that the difficulty of the subject consists. The faculty of Taste, plainly, is not a faculty like any of the external senses—the range of whose objects is limited and precise, as well as the qualities by which they are gratified or offended,—and Beauty, accordingly, is discovered in an infinite variety of objects, among which it seems, at first sight, impossible to discover any other bond of connexion. Yet boundless as their diversity may appear, it is plain that they *must* resemble each other in *something*, and in something more definite and definable than merely in being agreeable;—since they are all classed together, in every tongue and nation, under the common appellation of Beautiful, and are felt indeed to produce emotions in the mind that have some sort of kindred or affinity. The words Beauty and Beautiful, in short, must mean something; and are universally felt to mean something much more definite than agreeableness or gratification in general; and while it is confessedly by no means easy to describe or define what that something is, the force and clearness of our perception of it is demonstrated by the readiness with which we determine, in any particular instance, whether the object of a given pleasurable emotion is or is not properly described as Beauty.

What we have already said, we confess, appears to us conclusive against the idea of this Beauty being any fixed or inherent property of the objects to which it is ascribed, or itself the object of any separate and independent faculty; and we will no longer conceal from the reader what we take to be the true solution of the difficulty.

Solution proposed for this Difficulty.

In our opinion, then, our sense of Beauty depends entirely on our previous experience of simpler pleasures or emotions, and consists in the *suggestion* of agreeable or interesting sensations with which we had formerly been made familiar by the direct and intelligible agency of our common sensibilities;—and that vast variety of objects, to which we give the common name of Beautiful, become entitled to that appellation, merely because they all possess the power of recalling or reflecting those sensations of which they have been the accompaniments, or with which they have been associated in our imagination by any other more casual bond of connection. According to this view of the matter, therefore, Beauty is not an inherent property or quality of objects at all, but the result of the accidental relations in which they may stand to our experience of pleasures or emotions,—and does not depend upon any particular configuration of parts, proportions, or colours, in external things, nor upon the unity, coherence, or simplicity of intellectual creations,—but merely upon the associations which, in the case of every individual, may enable these inherent, and otherwise indifferent qualities, to suggest or recal to the mind emotions of a pleasur-

Beauty.

able or interesting description. It follows, therefore, that no object is beautiful in itself,—or could appear so, antecedent to our experience of direct pleasures or emotions; and that, as an infinite variety of objects may thus reflect interesting ideas, so all of them may acquire the title of Beautiful, although utterly diverse and disparate in their nature, and possessing nothing in common but this accidental power of reminding us of other emotions.

This theory, which, we believe, is now very generally adopted, though under many needless qualifications, shall be farther developed and illustrated in the sequel. But at present we shall only remark, that it serves at least to solve the great problem involved in the discussion, by rendering it easily conceivable how objects which have no inherent resemblance, nor, indeed, any one quality in common, should yet be united in one common relation, and consequently acquire one common epithet,—just as all the things that belonged to a beloved individual may serve to remind us of him, and thus to awake a kindred class of emotions, though just as unlike each other as any of the objects that are classed under the general name of Beautiful. His poetry, for instance, or his slippers,—his acts of bounty, or his saddlehorse,—may lead to the same chain of interesting remembrances, and thus agree in possessing a power of excitement, for the sources of which we should look in vain through all the variety of their physical or metaphysical qualities.

By the help of the same consideration, we get rid of all the mystery of a peculiar sense or faculty, imagined for the express purpose of perceiving Beauty; and discover that the power of Taste is nothing more than the habit of tracing those associations, by which almost all objects may be connected with interesting emotions. It is easy to understand, that the recollection of any scene of delight or emotion must produce a certain agreeable sensation, and that the objects which introduce these recollections should not appear altogether indifferent to us: Nor is it, perhaps, very difficult to imagine, that recollections thus strikingly suggested by some real and present existence, should present themselves under a different aspect, and move the mind somewhat differently from those which arise spontaneously in the ordinary course of our reflections, and do not thus grow out of a direct and peculiar impression.

The whole of this doctrine, however, we shall endeavour by and bye to establish upon more direct evidence; but having now explained, in a general way, both the difficulties of the subject, and our suggestion as to their true solution, it is proper that we should take a short review of the more considerable theories that have been proposed for the elucidation of this curious question; which is one of the most delicate, as well as the most popular in the science of metaphysics,—was one of the earliest which exercised the speculative ingenuity of philosophers,—and has at last, we think, been more successfully treated than any other of a similar description.

[…]ort historical View [of] the Theories pro[pos]ed on [the] Subject.

[Ge]neral [Re]marks [on] these [The]ories.

In most of these speculations, we shall find rather imperfect truth, than fundamental error:—or, at all events, such errors only as arise naturally from that peculiar difficulty which we have already endeavoured to explain, as consisting in the prodigious multitude and diversity of the objects in which the common quality of Beauty was to be accounted for. Those who have not been sufficiently aware of the difficulty have generally dogmatized from a small number of instances, and have rather given examples of the occurrence of Beauty in some few classes of objects, than afforded any light as to that upon which it essentially depended in all—while those who felt its full force have very often found no other resource, than to represent Beauty as consisting in properties so extremely vague and general (such, for example, as the power of exciting ideas of relation), as almost to elude our comprehension, and, at the same time, of so abstract and metaphysical a description, as not to be very intelligibly stated, as the radicals of a strong, familiar, and pleasurable emotion. This last observation leads us to make one other remark upon the general character of these theories; and this is, that some of them seem necessarily to imply the existence of a peculiar sense or faculty for the perception of Beauty; as they resolve it into properties that are not in any way interesting or agreeable to any of our known faculties. Such are all those which make it consist in Proportion,—or in Variety, combined with Regularity,—or in waving lines,—or in Unity,—or in the perception of Relations,—without explaining, or attempting to explain, how any of these things should affect us with any delight or emotion. Others, again, do not require the supposition of any such separate faculty; because in them the sense of Beauty is considered as arising from other more simple and familiar emotions, which are in themselves and beyond all dispute agreeable. Such are those which teach that Beauty depends on the perception of Utility, or of Design, or Fitness, or in tracing Associations between its objects and the common joys or emotions of our nature. Which of these two classes of speculation, to one or other of which, we believe, all theories of Beauty may be reduced, is the most philosophical in itself, we imagine can admit of no question; and we hope in the sequel to leave it as little doubtful, which is to be considered as most consistent with the fact. In the mean time, we must give a short account of some of the theories themselves.

Speculations of Plato on the Subject.

The most ancient of which it seems necessary to take any notice, is that which may be traced in the Dialogues of Plato,—though we are very far from pretending that it is possible to give any intelligible or consistent account of its tenor. It should never be forgotten, however, that it is to this subtle and ingenious spirit, that we owe the suggestion, that it is *Mind* alone that is Beautiful; and that, in perceiving Beauty, it only contemplates the shadow of its own affections;—a doctrine which, however mystically unfolded in his writings, or however combined with extravagant or absurd speculations, unquestionably carries in it the germ of all the truth that has since been revealed on the subject. By far the largest dissertation, however, that this great philosopher has left upon the nature of Beauty, is to be found in the dialogue entitled *the Greater Hippias*, which is entirely devoted to that inquiry. We do not learn a great deal of the author's own opinion, indeed, from this performance; for it is one of

Beauty.

the dialogues which have been termed *Anatreptic* or confuting,—in which nothing is concluded in the affirmative, but a series of sophistical suggestions or hypotheses are successively exposed. The plan of it is to lead on Hippias, a shallow and confident sophist, to make a variety of dogmatical assertions as to the nature of Beauty, and then to make him retract and abandon them upon the statement of some obvious objections. Socrates and he agree at first in the notable proposition, "that Beauty is that by which all Beautiful things are Beautiful;" and then, after a great number of suggestions, by far too childish and absurd to be worthy of any notice, such as, that the Beautiful may peradventure be gold, or a fine woman, or a handsome mare, they at last get to some suppositions, which show that almost all the theories that have since been propounded on this interesting subject, had occurred thus early to the active and original mind of this keen and curious inquirer. Thus Socrates first suggests, that Beauty may consist in the Fitness or suitableness of any object to the place it occupies, and afterwards, more generally and directly, that it may consist in Utility,—a notion which is ultimately rejected, however, upon the subtle consideration that the useful is that which produces good, and that the producer and the product being necessarily different, it would follow, upon that supposition, that beauty could not be good, nor good beautiful. Finally, he suggests, that Beauty may be the mere organic delight of the eye or the ear,—to which, after stating very slightly the objection, that it would be impossible to account upon this ground for the Beauty of poetry or eloquence, he proceeds to rear up a more refined and elaborate refutation, upon such grounds as these:—If Beauty be the proper name of that which is naturally agreeable to the sight and hearing, it is plain, that the objects to which it is ascribed must possess some common and distinguishable property, besides that of being agreeable, in consequence of which, they are separated and set apart from objects that are agreeable to our *other* senses and faculties, and, at the same time, classed together under the common appellation of Beautiful.—Now, we are not only quite unable to discover what this property is, but it is manifest, that objects which make themselves known to the ear, *can* have no property as such, in common with objects that make themselves known to the eye; it being impossible that an object which is beautiful by its colour, can be beautiful, from the same quality, with another which is beautiful by its sound. From all which it is inferred, that, as Beauty is admitted to be something real, it cannot be merely what is agreeable to the organs of sight or hearing.

There is no practical wisdom, we admit, in those fine drawn speculations; nor any of that spirit of patient observation by which alone any sound view of such objects can ever be attained. There are also many marks of that singular incapacity to distinguish between what is absolutely puerile and silly, and what is plausible, at least, and ingenious, which may be reckoned among the characteristics of "the divine philosopher," and in some degree of all the philosophers of antiquity: But they show clearly enough the subtle and abstract character of Greek speculation, and prove at how early a period, and to how great an extent, the inherent difficulties of the subject were felt, and produced their appropriate effects.

There are some hints on these subjects in the works of Xenophon, and some scattered observations in those of Cicero, who was the first, we believe, to observe, that the sense of Beauty is peculiar to Man;—but nothing else, we believe, in classical antiquity, which requires to be analyzed or explained. It appears that St Augustin composed a large treatise on Beauty; and it is to be lamented, that the speculations of that acute and ardent genius on such a subject have been lost. We discover, from incidental notices in other parts of his writings, that he conceived the Beauty of all objects to depend on their Unity,—or on the perception of that Principle or Design which fixed the relations of their various parts, and presented them to the intellect or imagination as one harmonious whole. It would not be fair to deal very strictly with a theory with which we are so imperfectly acquainted: But it may be observed, that, while the author is so far in the right as to make Beauty consist in a relation to mind, and not in any physical quality, he has taken far too narrow and circumscribed a view of the matter, and one which seems almost exclusively applicable to works of human art; it being plain enough, we think, that a beautiful landscape, or a beautiful horse, has no more unity, and no more traces of design, than one which is not beautiful.

Doctrine of St Augustin that Beauty consists in Unity.

We do not pretend to know what the Schoolmen taught upon this subject during the dark ages; but the discussion does not seem to have been resumed for long after the revival of letters. The followers of Leibnitz were pleased to maintain, that Beauty consisted in Perfection; but what constituted Perfection they did not attempt to define. M. Crouzas wrote a long essay, to show that Beauty depended on these five elements, Variety, Unity, Regularity, Order, and Proportion; and the Pere André, a still longer one to prove, that, admitting these to be the true foundations of Beauty, it was still most important to consider, that the Beauty which results from them is either Essential, or Natural, or Artificial,—and that it may be greater or less, according as the characteristics of each of these classes are combined or set in opposition.

Opinions of Crouzas and André.

Among ourselves, we are not aware of any considerable publication on the subject till the appearance of Lord Shaftesbury's *Characteristics*, in which a sort of rapturous Platonic doctrine is delivered as to the existence of a primitive and Supreme Good and Beauty, and of a certain internal sense, by which both Beauty and moral merit were distinguished. Addison published several ingenious papers in *The Spectator*, on the pleasures of the imagination, and was the first, we believe, who referred them to the specific sources of Beauty, Sublimity, and Novelty. He did not enter much, however, into the metaphysical discussion of the nature of Beauty itself; and the first philosophical treatise of note that appeared on the subject, may be said to have been the *Inquiry* of Dr Hucheson, first published, we believe, in 1725.

Of Lord Shaftesbury.

Of Addison.

Dr Hucheson's Doctrine of an internal reflex Sense by which Beauty is discovered.

In this work, the notion of a peculiar internal

Beauty.

sense, by which we are made sensible of the existence of Beauty, is very boldly promulgated, and maintained by many ingenious arguments: Yet nothing, we conceive, can be more extravagant than such a proposition; and nothing but the radical faults of the other parts of the hypothesis could possibly have driven the learned author to its adoption. Even after the existence of this sixth sense was assumed, he felt that it was still necessary that he should explain what were the qualities by which it was gratified; and these, he was pleased to allege, were nothing but the combinations of Variety with Uniformity; all objects, as he has himself expressed it, which are equally Uniform, being Beautiful in proportion to their Variety,—and all objects equally various being Beautiful in proportion to their Uniformity. Now, not to insist upon the obvious and radical objection that this is not true in fact, as to flowers, landscapes, or indeed of any thing but architecture, if it be true of that,—it could not fail to strike the ingenious author that these qualities of Uniformity and Variety were not of themselves agreeable to any of our known senses or faculties, except when considered as symbols of Utility or Design, and therefore could not intelligibly account for the very lively emotions which we often experience from the perception of Beauty, where the notion of design or utility was not at all suggested. He was constrained, therefore, either to abandon this view of the nature of Beauty altogether, or to imagine a new sense or faculty, whose characteristic and description it should be to receive delight from the combinations of Uniformity and Variety, without any consideration of their being significant of things agreeable to our other faculties; and this being accomplished by the mere force of the assumption and the definition, there was no room for farther dispute or difficulty in the matter.

[T]his Sense [e]xcited by [th]e combin[a]tion of [U]niformity [a]nd Varie[t]y.

[A]ttempts [to] resolve [B]eauty into [U]niformity [a]nd Variety [w]ithout the [su]pposition [of] a sepa[ra]te Sense.

Some of Hucheson's followers, such as Gerard and others, who were a little startled at the notion of a separate faculty, and yet wished to retain the doctrine of Beauty depending on Variety and Uniformity, endeavoured, accordingly, to show that these qualities were *naturally* agreeable to the mind, and were recommended by considerations arising from its most familiar properties. Uniformity or Simplicity, it is said, renders our conception of objects easy, and saves the mind from all fatigue and distraction in the consideration of them; whilst Variety, if circumscribed and limited by an ultimate uniformity, gives it a pleasing exercise and excitement, and keeps its energies in a state of pleasurable activity. Now, this appears to us to be mere trifling. The varied and lively emotions which we receive from the perception of Beauty, obviously have no sort of resemblance to the pleasure of moderate intellectual exertion; nor can anything be conceived more utterly dissimilar than the gratification we have in gazing on the form of a lovely woman, and the satisfaction we receive from working an easy problem in arithmetic or geometry. If a triangle is more beautiful than a regular polygon, as those authors maintain, merely because its figure is more easily comprehended, the number *four* should be more beautiful than the number three hundred and twenty-seven, and the form of a gibbet far more agreeable than that of a branching oak. The radical error, in short, consists in fixing upon properties that are not interesting in themselves, and can never be conceived, therefore, to excite any emotion, as the fountain-spring of all our emotions of Beauty: And it is an absurdity that must infallibly lead to others,—whether these take the shape of a violent attempt to disguise the truly indifferent nature of the properties so selected, or of the bolder expedient of creating a peculiar faculty, whose office it is to find them interesting.

[N]ot quite [s]atisfac[to]ry.

Theory of Burke, that things are Beautiful which produce a relaxation of the Fibres.

The next remarkable theory was that proposed by Edmund Burke, in his *Treatise of the Sublime and Beautiful.* But of this, in spite of the great name of the author, we cannot persuade ourselves that it is necessary to say much. His explanation is founded upon a species of materialism,—not much to have been expected from the general character of his genius, or the strain of his other speculations,—for it all resolves into this,—that all objects appear Beautiful, which have the power of producing a peculiar relaxation of our nerves and fibres, and thus inducing a certain degree of bodily languor and sinking. Of all the suppositions that have been at any time hazarded to explain the phenomena of Beauty, this, we think, is the most unfortunate, and the most weakly supported. There is no philosophy in the doctrine,—and the fundamental assumption is in every way contradicted by the most familiar experience. There is no relaxation of the fibres in the perception of Beauty,—and there is no pleasure in the relaxation of the fibres. If there were, it would follow, that a warm bath would be by far the most beautiful thing in the world—and that the brilliant lights, and bracing airs of a fine autumn morning, would be the very reverse of Beautiful. Accordingly, though the treatise alluded to will always be valuable on account of the many fine and just remarks it contains, we are not aware that there is any accurate inquirer into the subject (with the exception, perhaps, of Mr Price, in whose hands, however, the doctrine assumes a new character) by whom the fundamental principle of the theory has not been explicitly abandoned.

Of Diderot, that our Sense of Beauty is merely a perception of Relation.

A yet more extravagant doctrine was soon afterwards inculcated, and in a tone of great authority, in a long article from the brilliant pen of Diderot, in the French *Encyclopédie*, and one which exemplifies, in a very striking manner, the nature of the difficulties with which the discussion is embarrassed. This ingenious person, perceiving at once, that the Beauty which we ascribe to a particular class of objects, could not be referred to any peculiar and inherent quality in the objects themselves, but depended upon their power of exciting certain sentiments in our minds; and being, at the same time, at a loss to discover what common power could belong to so vast a variety of objects as pass under the general appellation of Beautiful, or by what tie all the various emotions which are excited by the perception of Beauty could be united, was at last driven, by his sense of the necessity of keeping his definition sufficiently wide and comprehensive, to hazard the strange assertion, that all objects were Beautiful which excite in us the idea of *relation;* that

our sense of Beauty consisted in tracing out the relations which the object possessing it might have to other objects; and that its Beauty was in proportion to the number and clearness of the relations thus suggested and perceived. It is scarcely necessary, we presume, to expose by any arguments the manifest fallacy, or rather the palpable absurdity of such a theory as this. In the first place, we conceive it to be obvious, that all objects whatever have an infinite, and consequently an equal number of relations, and are equally likely to suggest them to those to whom they are presented;—at all events, it is certain, that ugly and disagreeable objects have just as many relations as those that are agreeable, and ought, therefore, to be just as Beautiful, if the sense of Beauty consists in the perception of relations. In the next place, it seems to be sufficiently certain, from the experience and common feelings of all men, that the perception of relations among objects is not in itself accompanied by any pleasure whatever, and in particular has no conceivable resemblance to the emotion we receive from the perception of Beauty. When we perceive one ugly old woman sitting exactly opposite to two other ugly old women, and observe, at the same moment, that the first is as big as the other two taken together, we humbly conceive, that this clear perception of the relations in which these three Graces stand to each other, cannot well be mistaken for a sense of Beauty, and that it does not in the least abate or interfere with our sense of their ugliness. Finally, we may observe, that the sense of Beauty results instantaneously from the perception of the object; whereas the discovery of its relations to other objects must necessarily be a work of time and reflection, in the course of which the beauty of the object, so far from being created or brought into notice, must, in fact, be lost sight of and forgotten.

Theory of Father Buffier and Sir Joshua Reynolds,—that Beauty consisted in what was most common and familiar.

Another more plausible and ingenious theory was suggested by the Pere Buffier, and afterwards adopted and illustrated with great talent in the *Discourses* of Sir Joshua Reynolds. According to this doctrine, Beauty consists, as Aristotle held virtue to do, in mediocrity, or conformity to that which was most usual. Thus a beautiful nose, to make use of Dr Smith's very apt illustration of this doctrine, is one that is neither very long nor very short,—very straight nor very much bent,—but of an ordinary form and proportion, compared with all the extremes. It is the form, in short, which nature seems to have aimed at in all cases, though she has more frequently deviated from it than hit it; but deviating from it in all directions, all her deviations come nearer to it than they ever do to each other. Thus the most beautiful in every species of creatures bears the greatest resemblance to the whole species, while monsters are so denominated because they bear the least; and thus the Beautiful, though in one sense the rarest, as the exact medium is but seldom hit, is invariably the most common, because it is the central point from which all the deviations are the least remote. This view of the matter is adopted by Sir Joshua in its full extent, and is even carried so far by this great artist, that he does not scruple to conclude, "That if we were more used to deformity than Beauty, deformity would then lose the idea that is now annexed to it, and take that of Beauty;—just as we approve and admire fashions in dress, for no other reason than that we are used to them."

Now, not to dwell upon the very startling conclusion to which these principles must lead, viz. that things are Beautiful in proportion as they are ordinary; and that it is merely their familiarity which constitutes their Beauty, we would observe, in the first place, that the whole theory seems to have been suggested by a consideration of animal forms, or perhaps of the human figure exclusively. In these forms, it is quite true that great and monstrous deviations from the usual proportions are extremely disagreeable. But this, we have no doubt, arises entirely from some idea of pain or disaster attached to their existence, or from their obvious unfitness for the functions they have to perform. In vegetable forms, accordingly, these irregularities excite no such disgust; it being, in fact, the great object of culture, in almost all the more beautiful kinds, to produce what may be called monstrosities. And, in mineral substances, where the idea of suffering is still more completely excluded, it is notorious that, so far from the more ordinary configurations being thought the most Beautiful, this epithet is scarcely ever employed but to denote some rare and unusual combination of veins, colours, or dimensions. As to landscapes, again, and almost all the works of art, without exception, the theory is plainly altogether incapable of application. In what sense, for example, can it be said that the Beauty of natural scenery consists in mediocrity; or that these landscapes are the most Beautiful that are the most common? or what meaning can we attach to the proposition, that the most Beautiful building, or picture, or poem, is that which bears the nearest resemblance to all the individuals of its class, and is, upon the whole, the most ordinary and common?

To a doctrine which is liable to these obvious and radical objections, it is not perhaps necessary to make any other; but we must remark farther, first, That it necessarily supposes that our sense of Beauty is, in all cases, preceded by such a large comparison between various individuals of the same species, as may enable us to ascertain that average or mean form in which Beauty is supposed to consist; and, consequently, that we could never discover any object to be Beautiful antecedent to such a comparison; and, secondly, That, even if we were to allow that this theory afforded some explanation of the superior Beauty of any one object, compared with others of the same class, it plainly furnishes no explanation whatever of the superior Beauty of one class of objects compared with another. We may believe, if we please, that one peacock is handsomer than another, because it approaches more nearly to the average or mean form of peacocks in general; but this reason will avail us nothing whatever in explaining why any peacock is handsomer than any pelican or penguin. We may say, without manifest absurdity, that the most beautiful pig is that which has least of the extreme qualities that sometimes occur in the tribe; but it would be palpably absurd to give this reason, or any thing like it, for the superior Beauty of the tribe of antelopes or spaniels.

The notion, in short, seems to have been hastily

Beauty.

adopted by the ingenious persons who have maintained it, partly upon the narrow ground of the disgust produced by monsters in the animal creation, which has been already sufficiently explained,—and partly in consequence of the fallacy which lurks in the vague and general proposition of these things being beautiful which are neither *too* big nor *too* little, *too* massive nor *too* slender, &c.; from which it was concluded, that Beauty must consist in mediocrity:—not considering that the particle *too* merely denotes those degrees which are exclusive of Beauty, without in any way fixing what those degrees are. For the plain meaning of these phrases is, that the rejected objects are too massive or too slender *to be beautiful*; and, therefore, to say that an object is beautiful which is neither too big nor too little, &c. is really saying nothing more than that beautiful objects are such as are not in any degree ugly or disagreeable. The illustration as to the effects of use or custom in the article of dress is singularly inaccurate and delusive; the fact being, that we never admire the dress which we are most accustomed to see,—which is that of the common people,—but the dress of the few who are distinguished by rank or opulence; and that we require no more custom or habit to make us admire this dress, whatever it may be, than is necessary to associate it in our thoughts with the wealth and dignity of those who wear it.

Opinions of Dr Gerard, Dr Blair, &c.

We need say nothing in this place of the opinions expressed on the subject of Beauty by Dr Gerard, Dr Blair, and a whole herd of rhetoricians, because none of them pretend to have any new or original notions with regard to it, and, in general, have been at no pains to reconcile or render consistent the various accounts of the matter, which they have contented themselves with assembling and laying before their readers altogether, as affording among them the best explanation that could be offered of the question. Thus they do not scruple to say, that the sense of Beauty is sometimes produced by the mere organic affection of the senses of sight or hearing; at other times, by a perception of a kind of regular variety; and in other instances by the association of interesting conceptions;—thus abandoning altogether any attempt to answer the radical question,—how the feeling of Beauty should be excited by such opposite causes,—and confounding together, without any attempt at discrimination, those theories which imply the existence of a separate sense or faculty, and those which resolve our sense of Beauty into other more simple or familiar emotions.

Later and more important Speculations.

Of late years, however, we have had three publications on the subject of a far higher character,—we mean, Mr Alison's *Essays on the Nature and Principles of Taste*—Mr Payne Knight's *Analytical Inquiry* into the same subjects—and Mr Dugald Stewart's *Dissertations* on the Beautiful, and on Taste, in his volume of *Philosophical Essays*. All these works possess an infinite deal of merit, and have among them disclosed almost all the truth that is to be known on the subject; though, as it seems to us, with some little admixture of error, from which it will not, however, be difficult to separate it.

Mr Alison's Theory, that all the Beauty of Material Objects is to be referred to Association.

Mr Alison maintains, that all Beauty, or at least that all the Beauty of material objects, depends on the associations that may have connected them with the ordinary affections or emotions of our nature; and in this, which is the fundamental point of his theory, we conceive him to be no less clearly right, than he is convincing and judicious, in the copious and beautiful illustration by which he has sought to establish its truth. When he proceeds, however, to assert, that our sense of Beauty consists not merely in the suggestion of ideas of emotion, but in the contemplation of *a connected series* of such ideas, and indicates a state of mind in which the faculties, half active and half passive, are given up to a sort of reverie or musing, in which they may wander, though among kindred impressions, far enough from the immediate object of perception, we will confess that he not only seems to us to advance a very questionable proposition, but very essentially to endanger the evidence, as well as the consistency, of his general doctrine. We are far from denying, that, in minds of sensibility and of reflecting habits, the contemplation of beautiful objects will be apt, especially in moments of leisure, and when the mind is vacant, to give rise to such trains of thought, and to such protracted meditations; but we cannot possibly admit that their existence is necessary to the perception of Beauty, or that it is in this state of mind exclusively that the sense of Beauty exists. The perception of Beauty, on the contrary, we hold to be, in most cases, quite instantaneous, and altogether as immediate as the perception of the external qualities of the object to which it is ascribed. Indeed, it seems only necessary to recollect, that it is to a present material object that we actually ascribe and refer this Beauty, and that the only thing to be explained is, how this object comes to appear Beautiful. In the long train of interesting meditations, however, to which Mr Alison refers,—in the delightful reveries in which he would make the sense of Beauty consist,—it is obvious that we must soon lose sight of the external object which gave the first impulse to our thoughts; and though we may *afterwards* reflect upon it, with increased interest and gratitude, as the parent of so many charming images, it is impossible, we conceive, that the perception of *its* Beauty can ever depend upon a long series of various and shifting emotions.

Embarrassed by the supposition of connected Trains of Emotions.

It likewise occurs to us to observe, that if every thing was beautiful, which was the occasion of a train of ideas of emotion, it is not easy to see why objects that are called ugly should not be entitled to that appellation. If they are sufficiently ugly not to be viewed with indifference, they too will give rise to ideas of emotion, and those ideas are just as likely to run into trains and series, as those of a more agreeable description. Nay, as contrast itself is one of the principles of association, it is not at all unlikely, that, in the train of impressive ideas which the sight of ugly objects may excite, a transition may be ultimately made to such as are connected with pleasure; and, therefore, if the perception of the Beauty of the object which first suggested them depended upon its having produced a series of ideas of emotion, or even of agreeable emotions, there seems to be no good reason for doubting, that ugly objects may thus be as Beautiful as any other, and that Beauty and Ugliness may be one and the same thing. Such is the danger, as it appears to us, of deserting the ob-

Beauty.

ject itself, or going beyond its immediate effect and impression, in order to discover the sources of its Beauty. Our view of the matter is safer, we think, and far more simple. We conceive the object to be associated either in our past experience, or by some universal analogy, with pleasures, or emotions that upon the whole are pleasant; and that these associated pleasures are instantaneously suggested, as soon as the object is presented, and by the first glimpse of its physical properties, with which, indeed, they are consubstantiated and confounded in our sensations.

Mr Knight admits association as the chief ingredient of Beauty.

The work of Mr Knight is more lively, various, and discursive, than Mr Alison's—but not so systematic or conclusive. It is the cleverer book of the two,—but not the most philosophical discussion of the subject. He agrees with Mr Alison in holding the most important, and, indeed, the only considerable part of Beauty, to depend upon Association, and has illustrated this opinion with a great variety of just and original observation. But he maintains, and maintains stoutly, that there is a Beauty independent of association—prior to it, and more original and fundamental—the primitive and natural Beauty of Colours and Sounds. Now, this we look upon to be a heresy, and a heresy inconsistent with the very first principles of Catholic philosophy. We shall not stop at present to give our reasons for this opinion, which we shall illustrate at large before we bring this article to a close;—but we beg leave merely to suggest at present, that if our sense of Beauty be confessedly in most cases the mere image or reflection of pleasures or emotions that have been associated with objects in themselves indifferent, it cannot fail to appear strange that it should also on some few occasions be a mere organic or sensual gratification of the particular organs. Language, it is believed, affords no other example of so whimsical a combination of different objects under one appellation, or of the confounding of a direct physical sensation with the suggestion of a social or sympathetic moral feeling. We would observe also, that while Mr Knight stickles so violently for this alloy of the senses in the constitution of Beauty, he admits, unequivocally, that Sublimity is, in every instance, and in all cases, the effect of association alone. Yet Sublimity and Beauty, in any just or large sense, and with a view to the philosophy of either, are manifestly one and the same; nor is it conceivable to us, that, if Sublimity be *always* the result of an association with ideas of Power or Danger, Beauty can possibly be, in any case, the result of a mere pleasurable impulse on the nerves of the eye or the ear. We shall return, however, to this discussion hereafter. Of Mr Knight we have only further to observe, that we think he is not less heretical in maintaining, that we have no pleasure in sympathizing with distress or suffering, but only with mental energy; and that, in contemplating the Sublime, we are moved only with a sense of power and grandeur, and never with any feeling of terror or awe.—These errors, however, are less intimately connected with the subject of our present discussion.

But maintains that there is a primitive and independent Beauty in Colours and Sounds.

Mr Stewart's Essay on the Beautiful, chiefly philological.

With Mr Stewart we have less occasion for quarrel; chiefly, perhaps, because he has made fewer positive assertions, and entered less into the matter of controversy. His *Essay* on the Beautiful is rather philological than metaphysical. The object of it is to show by what gradual and successive extensions of meaning the word, though at first appropriated to denote the pleasing effect of *colours* alone, might naturally come to signify all the other pleasing things to which it is now applied. In this investigation he makes many admirable remarks, and touches, with the hand of a master, upon many of the disputable parts of the question; but he evades the particular point at issue between us and Mr Knight, by stating, that it is quite immaterial to his purpose, whether the Beauty of colours be supposed to depend on their organic effect on the eye, or on some association between them and other agreeable emotions,—it being enough for his purpose that this was probably the first sort of Beauty that was observed, and that to which the name was at first exclusively applied. It is evident to us, however, that he leans to the opinion of Mr Knight, as to this Beauty being truly sensual or organic. In observing, too, that Beauty is not now the name of any one thing or quality, but of very many different qualities,—and that it is applied to them all, merely because they are often united in the same objects, or perceived at the same time and *by the same organs*,—it appears to us that he carries his philology a little too far, and disregards other principles of reasoning of far higher authority. To give the name of Beauty, for example, to every thing that interests or pleases us through the channel of sight, including in this category the mere impulse of light that is pleasant to the organ, and the presentment of objects whose whole charm consists in awakening the memory of social emotions, seems to us to be confounding things together that must always be separate in our feelings, and giving a far greater importance to the mere identity of the organ of perception, than is warranted either by the ordinary language or ordinary experience of men. Upon the same principle we should give this name of Beautiful, and no other, to all acts of kindness or magnanimity, and, indeed, to every interesting occurrence which took place in our sight, or came to our knowledge by means of the eye:—nay, as the ear is also allowed to be a channel for impressions of Beauty, the same name should be given to any interesting or pleasant thing that we hear,—and good news read to us from the gazette should be denominated Beautiful, just as much as a fine composition of music. These things, however, are never called Beautiful, and are felt, indeed, to afford a gratification of quite a different nature. It is no doubt true, as Mr Stewart has observed, that Beauty is not one thing, but many,—and does not produce one uniform emotion, but an infinite variety of emotions. But this we conceive is not merely because many pleasant things may be intimated to us by the same sense, but because the things that are called Beautiful may be associated with an infinite variety of agreeable emotions, of the specific character of which their Beauty will consequently partake. Nor does it follow, from the fact of this great variety, that there can be no other principle of union among these agreeable emotions, but that of a *name*, extended to them all upon the very slight ground of their

Beauty.

Questionable Doctrine as to the extension of the name of Beautiful to pleasing Objects that address themselves to the same Sense.

Beauty.

coming through the same organ; since, upon our theory, and indeed upon Mr Stewart's, in a vast majority of instances, there is the remarkable circumstance of their being all *suggested* by association with some present sensation, and all modified and compounded to our feelings by an actual and direct perception.

It is unnecessary, however, to pursue these criticisms, or, indeed, this hasty review of the speculation of other writers, any farther. The few observations we have already made, will enable the intelligent reader, both to understand in a general way what has been already done on the subject, and in some degree prepare him to appreciate the merits of that theory, substantially the same with Mr Alison's, which we shall now proceed to illustrate somewhat more in detail.

Farther illustration of the Theory of Associations.

The basis of it is, that the Beauty which we impute to outward objects, is nothing more than the reflection of our own inward emotions, and is made up entirely of certain little portions of love, pity, and affection, which have been connected with these objects, and still adhere as it were to them, and move us anew whenever they are presented to our observation. Before proceeding to bring any proof of the truth of this proposition, there are two things that it may be proper to explain a little more distinctly. First, * What are the primary affections, by the suggestion of which we think the sense of Beauty is produced? And, secondly, What is the nature of the connexion by which we suppose that the objects we call beautiful are enabled to suggest these affections?

What Affections may be the basis of Beauty.

With regard to the first of these points, it fortunately is not necessary either to enter into any tedious details, or to have recourse to any nice distinctions. All sensations that are not absolutely indifferent, and are, at the same time, either agreeable, when experienced by ourselves, or attractive when contemplated in others, may form the foundation of the emotions of Sublimity or Beauty. The love of sensation seems to be the ruling appetite of human nature; and many sensations, in which the painful seems to bear no little share, are consequently sought for with avidity, and recollected with interest, even in our own persons. In the persons of others, emotions still more painful are contemplated with eagerness and delight; and therefore we must not be surprised to find, that many of the pleasing sensations of Beauty or Sublimity resolve themselves ultimately into recollections of feelings that may appear to have a very opposite character. The sum of the whole is, that every feeling which it is agreeable to experience, to recal, or to witness, may become the source of beauty in external objects, when it is so connected with them as that their appearance reminds us of that feeling. Now, in real life, and from daily experience and observation, we know that it is agreeable, in the first place, to recollect our own pleasurable sensations, or to be enabled to form a lively conception of the pleasures of other men, or even of sentient beings of any description. We know likewise, from the same sure authority, that there is a certain delight in the remembrance of our past, or the conception of our future emotions, even though attended with great pain, provided they be not forced too rudely on the mind, and be softened by the accompaniment of any milder feeling. And finally, we know, in the same manner, that the spectacle or conception of the emotions of others, even when in a high degree painful, is extremely interesting and attractive, and draws us away, not only from the consideration of indifferent objects, but even from the pursuit of light or frivolous enjoyments. All these are plain and familiar facts, of the existence of which, however they may be explained, no one can entertain the slightest doubt,—and into which, therefore, we shall have made no inconsiderable progress, if we can resolve the more mysterious fact, of the emotions we receive from the contemplation of Sublimity or Beauty.

Our proposition then is, that these emotions are not original emotions, nor produced directly by any qualities in the objects which excite them; but are reflections, or images, of the more radical and familiar emotions to which we have already alluded; and are occasioned, not by any inherent virtue in the objects before us, but by the accidents, if we may so express ourselves, by which these may have been enabled to suggest or recal to us our own past sensations or sympathies. We might almost venture, indeed, to lay it down as an axiom, that, except in the plain and palpable case of bodily pain or pleasure, we can never be *interested* in any thing but the fortunes of sentient beings;—and that every thing partaking of the nature of mental emotion, must have for its object the feelings, past, present or possible, of something capable of sensation. Independent, therefore, of all evidence, and without the help of any explanation, we should have been apt to conclude, that the emotions of Beauty and Sublimity must have for their objects the sufferings or enjoyments of sentient beings;—and to reject, as intrinsically absurd and incredible, the supposition, that material objects, which obviously do neither hurt nor delight the body, should yet excite, by their mere physical qualities, the very powerful emotions which are sometimes excited by the spectacle of Beauty.

Of the feelings, by their connexion with which external objects become beautiful, we do not think it necessary to speak more minutely;—and, therefore, it only remains, under this preliminary view of the subject, to explain the nature of that connexion by which we conceive this effect to be produced. Here, also, there is but little need for minuteness, or fulness of enumeration. Almost every tie, by which two objects can be bound together in the imagination, in such a manner as that the presentment of the one shall recal the memory of the other;—or, in

Nature of the associations by which objects appear Beautiful.

* A considerable part of the sequel of this article has already appeared in a critique (by the same author) upon Mr Alison's *Essay* in the *Edinburgh Review* for May 1811.

other words, almost every possible relation which can subsist between such objects, may serve to connect the things we call Sublime or Beautiful, with feelings that are interesting or delightful. It may be useful, however, to class these bonds of association between Mind and Matter in a rude and general way.

It appears to us, then, that objects are Sublime or Beautiful, *First*, When they are the Natural signs, and Perpetual concomitants of pleasurable sensations, or, at any rate, of some lively feeling or emotion in ourselves or in some other sentient beings; or, *Secondly*, When they are the arbitrary or Accidental concomitants of such feelings; or, *Thirdly*, When they bear some Analogy or fanciful resemblance to things with which these emotions are necessarily connected. In endeavouring to illustrate the nature of these several relations, we shall be led to lay before our readers some proofs that appear to us satisfactory of the truth of the general theory.

First Class of Associations, where the external object is *necessarily* connected with the emotion.

The most obvious, and the strongest association that can be established between inward feelings and external objects is, where the object is Necessarily and Universally connected with the feeling by the law of nature, so that it is always presented to the senses when the feeling is impressed upon the mind,—as the sight or the sound of laughter, with the feeling of gaiety,—of weeping with distress,—of the sound of thunder, with ideas of danger and power. Let us dwell for a moment on the last instance.—Nothing, perhaps, in the whole range of nature, is more strikingly and universally sublime than the sound we have just mentioned; yet it seems obvious, that the sense of sublimity is produced, not by any quality that is perceived by the ear, but altogether by the impression of Power and of Danger that is necessarily made upon the mind, whenever that sound is heard. That it is not produced by any peculiarity in the sound itself, is certain, from the mistakes that are frequently made with regard to it. The noise of a cart rattling over the stones, is often mistaken for thunder; and as long as the mistake lasts, this very vulgar and insignificant noise is actually felt to be prodigiously sublime. It is so felt, however, it is perfectly plain, merely because it is then associated with ideas of prodigious power and undefined danger;—and the sublimity is destroyed, the moment the association is dissolved, though the sound itself, and its effect on the organ, continue exactly the same. This, therefore, is an instance in which sublimity is distinctly proved to consist, not in any physical quality of the object to which it is ascribed, but in its necessary connexion with that vast and uncontrolled Power which is the natural object of awe and veneration.

Example.

Other Examples. Beauty of the Human Countenance.

We may now take an example a little less plain and elementary. The most beautiful object in nature, perhaps, is the countenance of a young and beautiful woman;—and we are apt at first to imagine, that, independent of all associations, the forms and colours which it displays are, in themselves, lovely and engaging, and would appear charming to all beholders, with whatever other qualities or impressions they might happen to be connected. A very little reflection, however, will probably be sufficient to convince us of the fallacy of this impression; and to satisfy us, that what we admire is not a combination of forms and colours, which could never excite any mental emotion, but a collection of signs and tokens of certain mental feelings and affections, which are universally recognised as the proper objects of love and sympathy. Laying aside the emotions arising from difference of sex, and supposing female beauty to be contemplated by the pure and unenvying eye of a female, it seems quite obvious, that, among its ingredients, we should trace the signs of two different sets of qualities, that are neither of them the object of sight, but of a higher faculty;—in the first place, of youth and health; and in the second place, of innocence, gaiety, sensibility, intelligence, delicacy or vivacity. Now, without enlarging upon the natural effect of these suggestions, we shall just suppose that the appearances, which must be admitted at all events to be actually significant of the qualities we have enumerated, had been by the law of nature attached to the very opposite qualities;—that the smooth forehead, the firm cheek, and the full lip, which are now so distinctly expressive to us of the gay and vigorous periods of youth,—and the clear and blooming complexion, which indicates health and activity, had been in fact the forms and colours by which old age and sickness were characterized; and that, instead of being found united to those sources and seasons of enjoyment, they had been the badges by which nature pointed out that state of suffering and decay which is now signified to us by the livid and emaciated face of sickness, or the wrinkled front, the quivering lip, and hollow cheek of age;—If this were the familiar law of our nature, can it be doubted that we should look upon these appearances, not with rapture, but with aversion,—and consider it as absolutely ludicrous or disgusting, to speak of the beauty of what was interpreted by every one as the lamented sign of pain and decrepitude? Mr Knight himself, though a firm believer in the intrinsic beauty of colours, is so much of this opinion, that he thinks it entirely owing to those associations that we prefer the tame smoothness, and comparatively poor colours of a youthful face, to the richly fretted and variegated countenance of a pimpled drunkard.

Such, we conceive, would be the inevitable effect of dissolving the subsisting connexion between the animating ideas of hope and enjoyment, and those visible appearances which are now significant of those emotions, and derive their whole Beauty from that signification. But the effect would be still stronger, if we could suppose the *moral* expression of those appearances to be reversed in the same manner. If the smile, which now enchants us, as the expression of innocence and affection, were the sign attached by nature to guilt and malignity,—if the blush which expresses delicacy, and the glance that speaks intelligence, vivacity and softness, had always been found united with brutal passion or idiot moodiness; is it not certain, that the whole of their Beauty would be extinguished, and that our emotions from the sight of them would be exactly the reverse of what they now are?

That the Beauty of a living and sentient creature should depend, in a great degree, upon qualities peculiar to such a creature, rather than upon the mere

Beauty.

physical attributes which it may possess in common with the inert matter around it, cannot indeed appear a very improbable supposition to any one. But it may be more difficult for some persons to understand how the beauty of mere dead matter should be derived from the feelings and sympathies of sentient beings. It is absolutely necessary, therefore, that we should give an instance or two of this derivation.

Of the Beauty of Inanimate Objects, and the Associations on which it depends—Beauty of Landscapes.

It is easy enough to understand how the sight of a picture or statue should affect us nearly in the same way as the sight of the original: nor is it much more difficult to conceive, how the sight of a cottage should give us something of the same feeling as the sight of a peasant's family; and the aspect of a town raise many of the same ideas as the appearance of a multitude of persons. We may begin, therefore, with an example a little more complicated. Take, for instance, the case of a common English landscape—green meadows with fat cattle—canals or navigable rivers—well fenced, well cultivated fields—neat, clean, scattered cottages—humble antique church, with church yard elms, and crossing hedgerows—all seen under bright skies, and in good weather:—There is much Beauty, as every one will acknowledge, in such a scene. But in what does the Beauty consist? Not certainly in the mere mixture of colours and forms; for colours more pleasing, and lines more graceful (according to any theory of grace that may be preferred), might be spread upon a board, or a painter's pallet, without engaging the eye to a second glance, or raising the least emotion in the mind;—but in the picture of human happiness that is presented to our imaginations and affections,—in the visible and unequivocal signs of comfort, and cheerful and peaceful enjoyment,—and of that secure and successful industry that ensures its continuance,—and of the piety by which it is exalted,—and of the simplicity by which it is contrasted with the guilt and the fever of a city life;—in the images of health and temperance and plenty which it exhibits to every eye,—and in the glimpses which it affords to warmer imaginations, of those primitive or fabulous times, when man was uncorrupted by luxury and ambition, and of those humble retreats in which we still delight to imagine that love and philosophy may find an unpolluted asylum. At all events, however, it is human feeling that excites our sympathy, and forms the object of our emotions. It is man, and man alone, that we see in the beauties of the earth which he inhabits;—or, if a more sensitive and extended sympathy connect us with the lower families of animated nature, and make us rejoice with the lambs that bleat on the uplands, or the cattle that ruminate in the valley, or even with the living plants that drink the bright sun and the balmy air beside them, it is still the idea of enjoyment—of feelings that animate the existence of sentient beings—that calls forth all our emotions, and is the parent of all the Beauty with which we proceed to invest the inanimate creation around us.

Instead of this quiet and tame *English* landscape, let us now take a Welch or a Highland scene; and see whether its beauties will admit of being explained on the same principle. Here, we shall have lofty mountains, and rocky and lonely recesses,—tufted woods hung over precipices,—lakes intersected with castled promontories,—ample solitudes of unploughed and untrodden valleys,—nameless and gigantic ruins,—and mountain echoes repeating the scream of the eagle and the roar of the cataract. This, too, is beautiful;—and, to those who can interpret the language it speaks, far more beautiful than the prosperous scene with which we have contrasted it. Yet, lonely as it is, it is to the recollection of man and of human feelings that its Beauty also is owing. The mere forms and colours that compose its visible appearance, are no more capable of exciting any emotion in the mind, than the forms and colours of a Turkey carpet. It is sympathy with the present or the past, or the imaginary *inhabitants* of such a region, that alone gives it either interest or Beauty; and the delight of those who behold it, will always be found to be in exact proportion to the force of their imaginations, and the warmth of their social affections. The leading impressions, here, are those of romantic seclusion, and primeval simplicity; lovers sequestered in these blissful solitudes, "from towns and toils remote,"—and rustic poets and philosophers communing with nature, at a distance from the low pursuits and selfish malignity of ordinary mortals;—then there is the sublime impression of the Mighty Power which piled the massive cliffs upon each other, and rent the mountains asunder, and scattered their giant fragments at their base;—and all the images connected with the monuments of ancient magnificence and extinguished hostility,—the feuds, and the combats, and the triumphs of its wild and primitive inhabitants, contrasted with the stillness and desolation of the scenes where they lie interred;—and the romantic ideas attached to their ancient traditions, and the peculiarities of their present life,—their wild and enthusiastic poetry,—their gloomy superstitions,—their attachment to their chiefs,—the dangers, and the hardships and enjoyments of their lonely huntings and fishings,—their pastoral shielings on the mountains in summer,—and the tales and the sports that amuse the little groups that are frozen into their vast and trackless valleys in the winter. Add to all this, the traces of vast and obscure antiquity that are impressed on the language and the habits of the people, and on the cliffs, and caves, and gulfy torrents of the land; and the solemn and touching reflection, perpetually recurring, of the weakness and insignificance of perishable man, whose generations thus pass away into oblivion, with all their toils and ambition, while Nature holds on her unvarying course, and pours out her streams, and renews her forests, with undecaying activity, regardless of the fate of her proud and perishable sovereign.

Beauty of Spring.

We have said enough, we believe, to let our readers understand what we mean by external objects being the natural signs or concomitants of human sympathies or emotions. Yet we cannot refrain from adding one other illustration, and asking on what other principle we can account for the beauty of Spring? Winter has shades as deep, and colours as brilliant; and the great forms of nature are substan-

Beauty.

tially the same through all the revolutions of the year. We shall seek in vain, therefore, in the accidents of mere organic matter, for the sources of that "vernal delight and joy," which subject all finer spirits to an annual intoxication, and strike home the sense of Beauty even to hearts that seem proof against it under all other aspects. And it is not among the Dead but among the Living, that this Beauty originates. It is the renovation of life and of joy to all animated beings, that constitutes this great jubilee of nature;—the young of animals bursting into existence,—the simple and universal pleasures which are diffused by the mere temperature of the air, and the profusion of sustenance,—the pairing of birds,—the cheerful resumption of rustic toils,—the great alleviation of all the miseries of poverty and sickness,—our sympathy with the young life, and the promise and the hazards of the vegetable creation,—the solemn, yet cheering, impression of the constancy of Nature to her great periods of renovation,—and the hopes that dart spontaneously forward into the new circle of exertions and enjoyments that is opened up by her hand and her example. Such are some of the conceptions that are forced upon us by the appearances of returning Spring; and that seem to account for the emotions of delight with which these appearances are hailed, by every mind endowed with any degree of sensibility, somewhat better than the brightness of the colours, or the agreeableness of the smells that are then presented to our senses.

Of Childhood.

They are kindred conceptions that constitute all the beauty of Childhood. The forms and colours that are peculiar to that age, are not necessarily or absolutely beautiful in themselves; for, in a grown person, the same forms and colours would be either ludicrous or disgusting. It is their indestructible connexion with the engaging ideas of innocence,—of careless gaiety,—of unsuspecting confidence;—made still more tender and attractive by the recollection of helplessness, and blameless and happy ignorance,—of the anxious affection that watches over all their ways,—and of the hopes and fears that seek to pierce futurity, for those who have neither fears nor cares nor anxieties for themselves.

These few illustrations will probably be sufficient to give our readers a general conception of the character and the grounds of that theory of beauty which we think affords the only true or consistent account of its nature. They are all examples, it will be observed, of the *First* and most important connexion which we think may be established between external objects and the sentiments or emotions of the mind; or cases, in which the visible phenomena are the Natural and Universal accompaniments of the emotion, and are consequently capable of reviving that emotion, in some degree, in the breast of every beholder. If the tenor of those illustrations has been such as to make any impression in favour of the general theory, we conceive that it must be very greatly confirmed by the slightest consideration of the *Second* class of cases, or those in which the external object is not the natural and necessary, but only the occasional or accidental concomitant of the emotion which it recals. In the former instances, some conception of beauty seems to be inseparable from the appearance of the objects; and being impressed, in some degree, upon all persons to whom they are presented, there is evidently room for insinuating that it is an independent and intrinsic quality of their nature, and does not arise from association with any thing else. In the instances, however, to which we are now to allude, this perception of Beauty is not universal, but entirely dependent upon the opportunities which each individual has had to associate ideas of emotion with the object to which it is ascribed;—the same thing appearing Beautiful to those who have been exposed to the influence of such associations, and indifferent to those who have not. Such instances, therefore, really afford an *experimentum crucis* as to the truth of the theory in question; nor is it easy to conceive any more complete evidence, both that there is no such thing as absolute or intrinsic Beauty, and that it depends altogether on those associations with which it is thus found to come and to disappear.

Second Class of Associations,—where the Beauty is derived from Associations not universal.

Importance of these instances.

Diversity of *National* Tastes, one striking example.

The accidental or arbitrary relations that may thus be established between natural sympathies or emotions, and external objects, may be either such as occur to whole classes of men, or are confined to particular individuals. Among the former, those that apply to different nations or races of men, are the most important and remarkable; and constitute the basis of those peculiarities by which National Tastes are distinguished. Take, again, for example, the instance of female Beauty,—and think what different and inconsistent standards would be fixed for it in the different regions of the world;—in Africa, in Asia, and in Europe;—in Tartary and in Greece; in Lapland, Patagonia and Circassia. If there was any thing absolutely or intrinsically Beautiful, in any of the forms thus distinguished, it is inconceivable that men should differ so outrageously in their conceptions of it: If Beauty were a real and independent quality, it seems impossible that it should be distinctly and clearly felt by one set of persons, where another set, altogether as sensitive, could see nothing but its opposite; and if it were actually and inseparably attached to certain forms, colours, or proportions, it must appear utterly inexplicable that it should be felt and perceived in the most opposite forms and proportion, in objects of the same description. On the other hand, if all Beauty consist in reminding us of certain natural sympathies and objects of emotion, with which they have been habitually connected, it is easy to perceive how the most different forms should be felt to be equally Beautiful. If female Beauty, for instance, consist in the visible signs and expressions of youth and health, and of gentleness, vivacity, and kindness; then it will necessarily happen, that the forms, and colours and proportions which nature may have connected with those qualities, in the different climates or regions of the world, will all appear equally Beautiful to those who have been accustomed to recognise them as the signs of such qualities; while they will be respectively indifferent to those who have not learned to interpret them in this sense, and displeasing to those whom experience has led to consider them as the signs of opposite qualities. The case is

Beauty.

the same, though perhaps to a smaller degree, as to the peculiarity of National Taste in other particulars. The style of dress and architecture in every nation, if not adopted from mere want of skill, or penury of materials, always appears Beautiful to the natives, and somewhat monstrous and absurd to foreigners;—and the general character and aspect of their landscape, in like manner, if not associated with substantial evils and inconveniencies, always appears more beautiful and enchanting than the scenery of any other region. The fact is still more striking, perhaps, in the case of Music;—in the effects of those national airs, with which even the most uncultivated imaginations have connected so many interesting recollections; and in the delight with which all persons of sensibility catch the strains of their native melodies in strange or in distant lands. It is owing chiefly to the same sort of arbitrary and national association, that white is thought a gay colour in Europe, where it is used at weddings,—and a dismal colour in China, where it is used for mourning;—that we think yew-trees gloomy, because they are planted in churchyards,—and large masses of powdered horsehair majestic, because we see them on the heads of judges and bishops.

Effects of Education on Taste, another.

Next to those curious instances of arbitrary or limited associations that are exemplified in the diversities of National taste, are those that are produced by the differences of instruction or Education. If external objects were sublime or beautiful in themselves, it is plain, that they would appear equally so to those who were acquainted with their origin, and to those to whom it was unknown. Yet it is not easy, perhaps, to calculate the degree to which our notions of Beauty and Sublimity are now influenced, over all Europe, by the study of Classical literature; or the number of impressions of this sort which the well-educated consequently receive, from objects that are utterly indifferent to uninstructed persons of the same natural sensibility. We gladly avail ourselves, upon this subject, of the beautiful expressions of Mr Alison.

"The delight which most men of education receive from the consideration of antiquity, and the beauty that they discover in every object which is connected with ancient times, is in a great measure to be ascribed to the same cause. The antiquarian, in his cabinet, surrounded by the relics of former ages, seems to himself to be removed to periods that are long since past, and indulges in the imagination of living in a world, which, by a very natural kind of prejudice, we are always willing to believe was both wiser and better than the present. All that is venerable or laudable in the history of these times, present themselves to his memory. The gallantry, the heroism, the patriotism of antiquity, rise again before his view, softened by the obscurity in which they are involved, and rendered more seducing to the imagination by that obscurity itself, which, while it mingles a sentiment of regret amid his pursuits, serves at the same time to stimulate his fancy to fill up, by its own creation, those long intervals of time of which history has preserved no record. The relics he contemplates, seem to approach him still nearer to the ages of his regard. The dress, the furniture, the arms of the times, are so many assistances to his imagination, in guiding or directing its exercise; and, offering him a thousand sources of imagery, provide him with an almost inexhaustible field in which his memory and his fancy may expatiate. There are few men who have not felt somewhat, at least, of the delight of such an employment. There is no man in the least acquainted with the history of antiquity, who does not love to let his imagination loose on the prospect of its remains, and to whom they are not in some measure sacred, from the innumerable images which they bring. Even the peasant, whose knowledge of former times extends but to a few generations, has yet in his village some monument of the deeds or virtues of his forefathers; and cherishes, with a fond veneration, the memorial of those good old times to which his imagination returns with delight, and of which he loves to recount the simple tales that tradition has brought him.

"And what is it that constitutes that emotion of sublime delight, which every man of common sensibility feels upon the first prospect of Rome? It is not the scene of destruction which is before him. It is not the Tiber, diminished in his imagination to a paltry stream, flowing amid the ruins of that magnificence which it once adorned. It is not the triumph of superstition over the wreck of human greatness, and its monuments erected upon the very spot where the first honours of humanity have been gained. It is ancient Rome which fills his imagination. It is the country of Cæsar, and Cicero, and Virgil, which is before him. It is the mistress of the world which he sees, and who seems to him to rise again from her tomb, to give laws to the universe. All that the labours of his youth, or the studies of his maturer age have acquired, with regard to the history of this great people, open at once before his imagination, and present him with a field of high and solemn imagery, which can never be exhausted. Take from him these associations,—conceal from him that it is Rome that he sees, and how different would be his emotion!"

The influences of the same studies may be traced, indeed, through almost all our impressions of Beauty,—and especially in the feelings which we receive from the contemplation of rural scenery; where the images and recollections which have been associated with such objects, in the enchanting strains of the poets, are perpetually recalled by their appearance, and give an interest and a Beauty to the prospect, of which the uninstructed cannot have the slightest perception. Upon this subject, also, Mr Alison has expressed himself with his usual warmth and elegance. After observing, that, in childhood, the Beauties of nature have scarcely any existence for those who have as yet but little general sympathy with mankind, he proceeds to state, that they are usually first recommended to notice by the poets, to whom we are introduced in the course of education; and who, in a manner, create them for us, by the associations which they enable us to form with their visible appearance.

"How different, from this period, become the sentiments with which the scenery of nature is contemplated, by those who have any imagination!

Beauty.

The beautiful forms of ancient mythology, with which the fancy of poets peopled every element, are now ready to appear to their minds, upon the prospect of every scene. The descriptions of ancient authors, so long admired, and so deserving of admiration, occur to them at every moment, and with them, all those enthusiastic ideas of ancient genius and glory, which the study of so many years of youth so naturally leads them to form. Or, if the study of modern poetry has succeeded to that of the ancient, a thousand other beautiful associations are acquired, which, instead of destroying, serve easily to unite with the former, and to afford a new source of delight. The awful forms of Gothic superstition, the wild and romantic imagery, which the turbulence of the middle ages, the Crusades, and the institution of Chivalry have spread over every country of Europe, arise to the imagination in every scene; accompanied with all those pleasing recollections of prowess, and adventure, and courteous manners, which distinguished those memorable times. With such images in their minds, it is not common nature that appears to surround them. It is nature embellished and made sacred by the memory of Theocritus and Virgil, and Milton and Tasso; their genius seems still to linger among the scenes which inspired it, and to irradiate every object where it dwells; and the creation of their fancy seem the fit inhabitants of that nature, which their descriptions have clothed with beauty."

Other Effects.

It is needless, for the purpose of mere illustration, to pursue this subject of arbitrary or accidental association though all the divisions of which it is susceptible; and, indeed, the task would be endless; since there is scarcely any class in society which could not be shown to have peculiar associations of interest and emotion with objects which are not so connected in the minds of any other class. The young and the old—the rich and the poor—the artist and the man of science—the inhabitant of the city and the inhabitant of the country—the man of business and the man of pleasure—the domestic and the dissipated,—nay, even the followers of almost every different study or profession, have perceptions of beauty, because they have associations with external objects, that are peculiar to themselves, and have no existence for any other persons. But, though the detail of such instances could not fail to show, in the clearest and most convincing manner, how directly the notion of beauty is derived from some more radical and familiar emotion, and how many and various are the channels by which such emotions are transmitted, enough, perhaps, has been already said, to put our readers in possession of the principles and general bearings of an argument which we must not think of exhausting.

The Effect of Fashion on our Opinion of the Beauty of Dress.

Before entirely leaving this branch of the subject, however, let us pause for a moment on the familiar but very striking and decisive instance of our varying and contradictory judgments, as to the Beauty of the successive fashions of dress that have existed within our own remembrance. All persons who still continue to find amusement in society, and are not old enough to enjoy only the recollections of their youth, think the prevailing fashions becoming and graceful, and the fashions of twenty or twenty-five years old intolerably ugly and ridiculous. The younger they are, and the more they mix in society, this impression is the stronger; and the fact is worth noticing, because there is really no one thing as to which persons judging merely from their feelings, and therefore less likely to be misled by any systems or theories, are so very positive and decided, as that established fashions are Beautiful in themselves; and that exploded fashions are intrinsically and beyond all question preposterous and ugly. We have never yet met a young lady or gentleman, who spoke from their hearts and without reserve, who had the least doubt on the subject, or could conceive how any person could be so stupid as not to see the intrinsic elegance of the reigning mode, or not to be struck with the ludicrous awkwardness of the habits in which their mothers were disguised. Yet there can be no doubt, that if these ingenious critics had been born, with the same natural sensibility to Beauty, but twenty years earlier, they would have joined in admiring what they now laugh at, as certainly as those who succeed them twenty years hereafter will laugh at them. It is plain, then, and we think scarcely disputed, out of the circles to which we have alluded, that there is, in the general case, no intrinsic Beauty or deformity in any of those fashions; and that the forms, and colours, and materials, that are, we may say, universally and very strongly felt to be Beautiful while they are in fashion, are sure to lose all their Beauty as soon as the fashion has passed away. Now the forms, and colours, and combinations, remain exactly as they were; and, therefore, it seems perfectly obvious, that the source of their successive Beauty and ugliness must be sought in something extrinsic, and can only be found in the associations which once recommended and ultimately degraded them in our estimation. While they were in fashion, they were the forms and colours which distinguished the rich and the noble, —the eminent, the envied, the observed in society. They were the forms and the colours in which all that was beautiful, and admired, and exalted, were habitually arrayed. They were associated, therefore, with ideas of opulence, and elegance, and gaiety, and all that is captivating and bewitching, in manners, fortune, and situation,—and derived the whole of their Beauty from those associations. By and bye, however, they were deserted by the beautiful, the rich, and the elegant, and descended to the vulgar and dependent, or were only seen in combination with the antiquated airs of faded beauties or obsolete beaux. They thus came to be associated with ideas of vulgarity and derision, and with the images of old and decayed persons, whom it is difficult for their juniors to believe ever to have been young or attractive;—and the associations being thus reversed, in which all their Beauty consisted, the Beauty itself naturally disappears.

The operation of the same causes is distinctly visible in all the other apparent irregularities of our judgments as to this description of Beauty. Old people have in general but little toleration for the obsolete fashions of their later or middle years; but will generally stickle for the intrinsic elegance of

those which were prevalent in the bright days of their early youth,—as being still associated in their recollections, with the beauty with which they were first enchanted, and the gay spirits with which they were then inspired. In the same way, while we laugh at the fashions of which fine ladies and gentlemen were proud in the days of our childhood, because they are now associated only with images of decrepitude and decay, we look with some feelings of veneration on the habits of more remote generations, the individuals of which are only known to us as historical persons; and with unmingled respect and admiration on those still more ancient habiliments which remind us either of the heroism of the feudal chivalry, or the virtue and nobleness of classical antiquity. The iron mail of the Gothic knight, or the clumsy shield and naked arms of the Roman warrior, strike us as majestic and graceful, merely because they are associated with nothing but tales of romantic daring or patriotic prowess,—while the full bottomed periwigs that were added to the soldier's equipment in the days of Lewis XIV. and King William,—and no doubt had a noble effect in the eyes of that generation,—now appear to us equally ridiculous and unbecoming, merely because such appendages are no longer to be seen, but upon the heads of sober and sedentary lawyers, or in the pictures of antiquated Esquires.

Associations peculiar to Individuals—their Effects.

We cannot afford, however, to enlarge any farther upon these considerations,—and are inclined indeed to think, that what has been already said on the subject of associations, which, though not universal, are common to whole classes of persons, will make it unnecessary to enlarge on those that are peculiar to each individual. It is almost enough, indeed, to transcribe the following short passage from Mr Alison.

"There is no man, who has not some interesting associations with particular scenes, or airs, or books, and who does not feel their beauty or sublimity enhanced to him by such connexions. The view of the house where one was born, of the school where one was educated, and where the gay years of infancy were passed, is indifferent to no man. They recal so many images of past happiness and past affections, they are connected with so many strong or valued emotions, and lead altogether to so long a train of feelings and recollections, that there is hardly any scene which one ever beholds with so much rapture. There are songs also, that we have heard in our infancy, which, when brought to our remembrance in after years, raise emotions for which we cannot well account; and which, though perhaps very indifferent in themselves, still continue from this association, and from the variety of conceptions which they kindle in our minds, to be our favourites through life. The scenes which have been distinguished by the residence of any person, whose memory we admire, produce a similar effect. *Movemur enim, nescio quo pacto, locis ipsis, in quibus eorum, quos diligimus, aut admiramur adsunt vestigia.* The scenes themselves may be little beautiful; but the delight with which we recollect the traces of their lives, blends itself insensibly with the emotions which the scenery excites; and the admiration which these recollections afford, seems to give a kind of sanctity to the place where they dwelt, and converts every thing into Beauty which appears to have been connected with them."

There are similar impressions,—as to the sort of scenery to which we have been long accustomed,—as to the style of personal beauty by which we were first enchanted,—and even as to the dialect, or the form of versification which we first begun to admire, that bestow a secret and adventitious charm upon all these objects, and enable us to discover in them a Beauty which is invisible, because it is non-existent to every other eye.

Third Class of Associations—those which depend on a certain analogy or affinity between mental qualities or emotions and external objects.

In all the cases we have hitherto considered, the external object is supposed to have acquired its Beauty, by being actually connected with the causes of our natural emotions, either as a sign of their existence, or as being locally present to their ordinary occasions. There is a relation, however, of another kind, to which it is necessary to attend, both to elucidate the general grounds of the theory, and to explain several appearances that might otherwise expose it to objections. This is the relation which external objects may bear to our internal feelings, and the power they may consequently acquire of suggesting them, in consequence of a sort of resemblance or analogy which they seem to have to their natural and appropriate objects. The language of poetry is founded, in a great degree, upon this analogy; and all language, indeed, is full of it; and attests, by its structure, both the extent to which it is spontaneously pursued, and the effects that are produced by its suggestion. We take a familiar instance from the elegant writer to whom we have already referred.

"What, for instance, is the impression we feel from the scenery of spring? The soft and gentle green with which the earth is spread, the feeble texture of the plants and flowers, and the remains of winter yet lingering among the woods and hills,—all conspire to infuse into our minds somewhat of that fearful tenderness with which infancy is usually beheld. With such a sentiment, how innumerable are the ideas which present themselves to our imagination! ideas, it is apparent, by no means confined to the scene before our eyes, or to the possible desolation which may yet await its infant beauty, but which almost involuntarily extend themselves to analogies with the life of man, and bring before us all those images of hope or fear, which, according to our peculiar situations, have the dominion of our hearts!—The Beauty of autumn is accompanied with a similar exercise of thought: The leaves begin then to drop from the trees; the flowers and shrubs, with which the fields were adorned in the summer months, decay; the woods and groves are silent; the sun himself seems gradually to withdraw his light, or to become enfeebled in his power. Who is there, who, at this season, does not feel his mind impressed with a sentiment of melancholy? or who is able to resist that current of thought, which, from such appearances of decay, so naturally leads him to the solemn imagination of that inevitable fate, which is to bring on alike the decay of life, of empire, and of nature itself."

A thousand such analogies, indeed, are suggested

Farther Illustrations.

to us by the most familiar aspects of nature. The morning and the evening present the same ready picture of youth and of closing life, as the various vicissitudes of the year. The withering of flowers images out to us the languor of beauty, or the sickness of childhood. The loud roar of troubled waters seems to bear some resemblance to the voice of lamentation or violence; and the softer murmur of brighter streams, to be expressive of cheerfulness and innocence. The purity and transparency of water or of air, indeed, is itself felt to be expressive of mental purity and gaiety; and their darkness or turbulence, of mental gloom and dejection. The genial warmth of autumn suggests to us the feeling of mild benevolence;—the sunny gleams and fitful showers of early spring, remind us of the waywardness of infancy;—flowers waving on their slender stems, impress us with the notion of flexibility and lightness of temper. All fine and delicate forms are typical of delicacy and gentleness of character; and almost all forms, bounded by waving or flowing lines, suggest ideas of ease, pliability, and elegance. Rapid and impetuous motion seems to be emblematical of violence and passion;—slow and steady motion, of deliberation, dignity, and resolution;—fluttering motion, of inconstancy or terror;—and waving motion, according as it is slow or swift, of sadness or playfulness. A lofty tower or a massive building gives us the idea of firmness and elevation of character;—a rock battered by the waves, of fortitude in adversity. Stillness and calmness in the water or the air, seem to shadow out tenderness, indolence, and placidity;—moonlight we call pensive and gentle;—and the unclouded sun gives us an impression of exulting vigour, and domineering ambition and glory.

It is not difficult, with the assistance which language affords us, to trace the origin of all these, and a thousand other associations. In many instances, the qualities which thus suggest mental emotions, do actually resemble their constant concomitants in human nature, as is obviously the case with the forms and motions which are sublime or beautiful; and, in some, their effects and relations bear so obvious an analogy to those of human conduct or feeling, as to force itself upon the notice of the most careless beholder. But, whatever may have been their original, the very structure of language attests the vast extent to which they have been carried, and the nature of the suggestions to which they are indebted for their interest or beauty. If we speak familiarly of the sparkling of wit—and the darkness of melancholy—can it be at all difficult to conceive that bright light may be agreeable, because it reminds us of gaiety,—and darkness oppressive, because it is felt to be emblematical of sorrow? It is very remarkable, indeed, that, while almost all the words by which the affections of the mind are expressed, seem to have been borrowed originally from the qualities of matter, the epithets by which we learn afterwards to distinguish such material objects as are felt to be Sublime or Beautiful, are all of them epithets that had been previously appropriated to express some quality or emotion of mind. Colours are said to be gay or grave—motions to be lively, or deliberate, or capricious—forms to be delicate or modest—sounds to be animated or mournful—prospects to be cheerful or melancholy—rocks to be bold—waters to be tranquil—and a thousand other phrases of the same import; all indicating, most unequivocally, the sources from which our interest in matter is derived, and proving, that it is necessary, in all cases, to confer mind and feeling upon it, before it can be conceived as either sublime or beautiful. The great charm, indeed, and the great secret of poetical diction, consists in thus lending life and emotion to all the objects it embraces; and the enchanting beauty which we sometimes recognise in descriptions of very ordinary phenomena, will be found to arise from the force of imagination, by which the poet has connected with human emotions, a variety of objects, to which common minds could not discover their relation. What the poet does for his readers, however, by his original similies and metaphors in these higher cases, even the dullest of these readers do, in some degree, every day, for themselves; and the Beauty which is perceived, when natural objects are unexpectedly vivified by the glowing fancy of the former, is precisely of the same kind that is felt when the closeness of the analogy enables them to force human feelings upon the recollection of all mankind. As the poet sees more of Beauty in nature than ordinary mortals, just because he perceives more of these analogies and relations to social emotion, in which all Beauty consists; so, other men see more or less of this Beauty, exactly as they happen to possess that fancy, or those habits, which enable them readily to trace out these relations.

Existence of such analogies indisputably proved by the structure of Language in all Countries.

From all these sources of evidence, then, we think it is pretty well made out, that the Beauty or Sublimity of external objects is nothing but the reflection of emotions excited by the feelings or condition of sentient beings; and is produced altogether by certain little portions, as it were, of love, joy, pity, veneration, or terror, that adhere to those objects that are present on occasion of such emotions.—Nor, after what we have already said, does it seem to be necessary to reply to more than one of the objections to which we are aware that this theory is liable.—If Beauty be nothing more than a reflection of love, pity, or veneration, how comes it, it may be asked, to be distinguished from these sentiments? They are never confounded with each other, either in our feelings or our language:—Why, then, should they all be confounded under the common name of Beauty? and why should Beauty, in all cases, affect us in a way so different from the love or compassion of which it is said to be merely the reflection?

Objection—that the sense of Beauty is different from the emotions into which it is here resolved.

Now, to these questions, we are somewhat tempted to answer, after the manner of our country, by asking, in our turn, whether it be really true, that Beauty always affects us in one and the same manner, and always in a different manner from the simple and elementary affections which it is its office to recal to us? In very many cases, it appears to us, that the sensations which we receive from objects that are felt to be Beautiful, and that in the highest degree, do not differ at all from the direct movements of tenderness or pity towards sentient beings. If the epithet of Beauty be correctly (as it is universally) applied to many of the most admired and en-

Answered, that it is not alway[s]

Beauty.

chanting passages in poetry, which consist entirely in the expression of affecting sentiments, the question would be speedily decided; and it is a fact, at all events, too remarkable to be omitted, that some of the most powerful and delightful emotions that are uniformly classed under this name, arise altogether from the direct influence of these pathetic emotions, without the intervention of any material imagery. We do not wish, however, to dwell upon an argument, which certainly is not applicable to all parts of the question; and, admitting that, on many occasions, the feelings which we experience from Beauty, are sensibly different from the primary emotions in which we think they originate, we shall endeavour, in a very few words, to give an explanation of this difference, which seems to be perfectly consistent with the theory we have undertaken to illustrate.

nd explained, here it is.

In the first place, it should make some difference on the primary affections to which we have alluded, that, in the cases alluded to, they are *reflected* from material objects, and not directly excited by their natural causes. The light of the moon has a very different complexion from that of the sun;—though it is in substance the sun's light; and glimpses of interesting, or even of familiar objects, caught unexpectedly from a mirror placed at a distance from these objects, will affect us, like sudden allusions in poetry, very differently from the natural perception of those objects in their ordinary relations. In the next place, the emotion, when suggested in the shape of Beauty, comes upon us, for the most part, disencumbered of all those accompaniments which frequently give it a peculiar and less satisfactory character, when it arises from direct intercourse with its living objects. The compassion, for example, that is suggested by Beauty of a gentle and winning description, is not attended with any of that disgust and uneasiness which frequently accompany the spectacle of real distress; nor with that importunate suggestion of the duty of relieving it, from which it is almost inseparable. Nor does the temporary delight which we receive from Beauty of a gay and animating character, call upon us for any such expenditure of spirits, or active demonstrations of sympathy, as are sometimes demanded by the turbulence of real joy. In the third place, the emotion of Beauty, being partly founded upon illusion, is far more transitory in its own nature, and is both more apt to fluctuate and vary in its character, and more capable of being dismissed at pleasure, than any of the primary affections, whose shadow and representative it is. In the fourth place, the perception of Beauty implies a certain exercise of the imagination that is not required in the case of direct emotion, and is sufficient, of itself, both to give a new character to every emotion that is suggested by the intervention of such an exercise, and to account for our classing all the various emotions that are so suggested under the same denomination of Beauty. When we are injured, we feel indignation,—when we are wounded, we feel pain,—when we see suffering, we feel compassion,—and when we witness any splendid act of heroism or generosity, we feel admiration—without any effort of the imagination, or the intervention of any picture or vision in the mind. But when we feel indignation, or pity, or admiration, in consequence of seeing some piece of inanimate matter that merely suggests or recals to us the ordinary causes or proper objects of these emotions, it is evident that our fancy is kindled by a sudden flash of recollection; and that the effect is produced by means of a certain poetical creation that is instantly conjured up in the mind. It is this active and heated state of the imagination, and this divided and busy occupation of the mind, that constitute the great peculiarity of the emotions we experience from the perception of Beauty.

Beauty.

Finally, and this is perhaps the most important consideration of the whole, it should be recollected, that, along with the shadow or suggestion of associated emotions, there is always present a real and direct perception, which not only gives a force and liveliness to all the images which it suggests, but seems to impart to them some share of its own reality. That there is an illusion of this kind in the case, is sufficiently demonstrated by the fact, that we invariably ascribe the interest, which we think has been proved to arise wholly from these associations, to the object itself, as one of its actual and inherent qualities, and consider *its* beauty as no less a property belonging to it, than any of its physical attributes. The associated interest, therefore, is beyond all doubt confounded with the present perception of the object itself; and a livelier and more instant impression is accordingly made upon the mind, than if the interesting conceptions had been merely excited in the memory by the usual operation of reflection or voluntary meditation. Something analogous to this is familiarly known to occur in other cases. When we merely think of an absent friend, our emotions are incomparably less lively than when the recollection of him is suddenly suggested by the unexpected sight of his picture, of the house where he dwelt, or the spot on which we last parted from him,—and all these objects seem for the moment to wear the colours of our own associated affections. When Captain Cook's companions found, in the remotest corner of the habitable globe, a broken spoon with the word *London* stamped upon it, and burst into tears at the sight,—they proved how differently we are moved by emotions thus connected with the real presence of an actual perception, than by the mere recollection of the objects on which those emotions depend. Every one of them had probably thought of London every day since he left it, and many of them might have been talking of it with tranquillity but a little before this more effectual appeal was made to their sensibility.

If we add to all this, that there is necessarily something of vagueness and variableness in the emotions most generally excited by the perception of Beauty, and that the mind wanders with the eye, over the different objects which may supply these emotions, with a degree of unsteadiness, and half voluntary half involuntary fluctuation, we may come to understand how the effect not only should be essentially different from that of the simple presentment of any one interesting conception, but should acquire a peculiarity which entitles it to a dif-

ferent denomination. Most of the associations of which we have been last speaking, as being founded on the analogies or fanciful resemblances that are felt to exist between physical objects and qualities, and the interesting affections of mind, are intrinsically of this vague and wavering description,—and when we look at a fine landscape, or any other scene of complicated Beauty, a great variety of such images are suddenly presented to the fancy, and as suddenly succeeded by others, as the eye ranges over the different features of which it is composed, and feeds upon the charms which it discloses. Now, the direct perception, in all such cases, not only perpetually accompanies the associated emotions, but is inextricably confounded with them in our feelings, and is even recognised upon reflection as the cause, not merely of their unusual strength, but of the several peculiarities by which we have shown that they are distinguished. It is not wonderful, therefore, either that emotions so circumstanced should not be classed along with similar affections, under circumstances extremely different, or that the perception of present existence, thus mixed up, and indissolubly confounded with interesting conceptions, should between them produce a sensation of so distinct a nature as naturally to be distinguished by a peculiar name,—or that the *Beauty* which results from this combination should, in ordinary language, be ascribed to the objects themselves,—the presence and perception of which is a necessary condition of its existence.

What we have now said is enough, we believe, to give an attentive reader that general conception of the theory before us, which is all that we can hope to give in the narrow limits to which we are confined. It may be observed, however, that we have spoken only of those sorts of Beauty which we think capable of being resolved into some passion, or emotion, or pretty lively sentiment of our nature; and though these are undoubtedly the highest and most decided kinds of Beauty, it is certain that there are many things called beautiful which cannot claim so lofty a connexion. It is necessary, therefore, to observe, that, though every thing that excites any feeling worthy to be called an *emotion* by its beauty or sublimity, will be found to be related to the natural objects of human passions or affections, there are many things which are pleasing or agreeable enough to be called beautiful, in consequence of their relation merely to human Convenience and Comfort;—many others that please by suggesting ideas of human skill and ingenuity;—and many that obtain the name of Beautiful, by being associated with human fortune, vanity, or splendour. After what has been already said, it will not be necessary either to exemplify or explain these subordinate phenomena. It is enough merely to suggest, that they all please upon the same great principle of sympathy with human feelings; and are explained by the simple and indisputable fact, that we are pleased with the direct contemplation of human comfort, ingenuity, and fortune. All these, indeed, obviously resolve themselves into the great object of sympathy—human enjoyment. Convenience and comfort is but another name for a lower, but very indispensable ingredient of that emotion. Skill and ingenuity readily present themselves as means by which enjoyment may be promoted; and high fortune, and opulence, and splendour, pass, at least at a distance, for its certain causes and attendants. The beauty of Fitness and adaptation of parts, even in the works of nature, is derived from the same fountain,—partly by means of its obvious analogy to works of human skill, and partly by suggestions of that creative Power and Wisdom, to which human destiny is subjected. The feelings, therefore, associated with all those qualities, though scarcely rising to the height of emotion, are obviously in a certain degree pleasing or interesting; and when several of them happen to be united in one object, may accumulate to a very great degree of Beauty. It is needless, we think, to pursue these general propositions through all the details to which they so obviously lead. We shall confine ourselves, therefore, to a very few remarks upon the Beauty of Architecture,—and chiefly as an illustration of our general position.

Associations with ideas of comfort, genius, power, or splendour: also the sources of Beauty.

There are few things, about which men of *virtu* are more apt to rave, than the merits of the Grecian architecture; and most of those who affect an uncommon purity and delicacy of taste, talk of the intrinsic Beauty of its Proportions as a thing not to be disputed, except by barbarian ignorance and stupidity. Mr Alison, we think, was the first who gave a full and convincing refutation of this mysterious dogma; and, while he admits, in the most ample terms, the beauty of the objects in question, has shown, we think, in the clearest manner, that it arises entirely from the combination of the following associations:—1st, The association of utility, convenience, or fitness for the purposes of the building; 2d, Of security and stability, with a view to the nature of the materials; 3d, Of the skill and power requisite to mould such materials into forms so commodious; 4th, Of magnificence, and splendour, and expence; 5th, Of antiquity; and, 6thly, Of Roman and Grecian greatness. His observations are summed up in the following short sentence.

"The proportions," he observes, "of these orders, it is to be remembered, are distinct subjects of Beauty, from the ornaments with which they are embellished, from the magnificence with which they are executed, from the purposes of elegance they are intended to serve, or the scenes of grandeur they are destined to adorn. It is in such scenes, however, and with such additions, that we are accustomed to observe them; and, while we feel the effect of all these accidental associations, we are seldom willing to examine what are the causes of the complex emotion we feel, and readily attribute to the nature of the architecture itself, the whole pleasure which we enjoy. But, besides these, there are other associations we have with these forms, that still more powerfully serve to command our admiration; for they are the Grecian orders; they derive their origin from those times, and were the ornament of those countries which are most hallowed in our imaginations; and it is difficult for us to see them, even in their modern copies, without feeling them operate upon our minds as relics of those polished nations where they first arose, and of that greater people by whom they were afterwards borrowed."

This analysis is to us perfectly satisfactory. But, indeed, we cannot conceive any more complete refutation of the notion of an intrinsic and inherent Beauty in the proportions of the Grecian architecture, than the fact of the admitted Beauty of such very opposite proportions in the Gothic. Opposite as they are, however, the great elements of Beauty are the same in this style as in the other,—the impressions of religious awe and of chivalrous recollections, coming here in place of the classical associations which constitute so great a share of the interest of the former. It is well observed by Mr Alison, that the great Durability and Costliness of the productions of this art, have had the effect, in almost all regions of the world, of rendering their fashion permanent, after it had once attained such a degree of perfection as to fulfil its substantial purposes.

"Buildings," he observes, "may last, and are intended to last for centuries. The life of man is very inadequate to the duration of such productions; and the present period of the world, though old with respect to those arts which are employed upon perishable subjects, is yet young in relation to an art, which is employed upon so durable materials as those of architecture. Instead of a few years, therefore, centuries must probably pass before such productions demand to be renewed; and, long before that period is elapsed, the sacredness of antiquity is acquired by the subject itself, and a new motive given for the preservation of similar forms. In every country, accordingly, the same effect has taken place: and the same causes which have thus served to produce among us, for so many years, an uniformity of taste with regard to the style of Grecian architecture, have produced also among the nations of the East, for a much longer course of time, a similar uniformity of taste with regard to their ornamental style of architecture; and have perpetuated among them the same forms which were in use among their forefathers, before the Grecian orders were invented."

It is not necessary, we think, to carry these illustrations any farther: as the theory they are intended to explain, is now, we believe, universally adopted, though with some limitations, which we see no reason to retain. Those suggested by Mr Alison, we have already endeavoured to dispose of in the few remarks we have made upon his publication; and it only remains to say a word or two more upon Mr Knight's doctrine as to the primitive and independent Beauty of Colours, upon which we have already hazarded some remarks.

[...mina- of Mr ...ght's ...trine as ...e origi- ...nd in- ...endent ...uty of ...urs.]

Agreeing as he does with Mr Alison, and all modern inquirers, that the whole Beauty of objects consists, in the far greater number of instances, in the associations to which we have alluded, he still maintains, that some few visible objects affect us with a sense of Beauty in consequence of the pleasurable impression they make upon the sense—and that our perception of Beauty is, in these instances, a mere organic sensation. Now, we have already stated, that it would be something quite unexampled in the history either of mind or of language, if certain physical and bodily sensations should thus be confounded with moral and social feelings with which they had no connection, and pass familiarly under one and the same name. Beauty consists confessedly, in almost all cases, in *the suggestion* of moral or social emotions, mixed up and modified by a present sensation or perception; and it is this suggestion, and this identification with a present object, that constitutes its essence, and gives a common character to the whole class of feelings it produces, sufficient to justify their being designated by a common appellation. If the word Beauty, in short, must mean something, and if *this* be very clearly what it means in all remarkable instances, it is difficult to conceive, that it should occasionally mean something quite different, and denote a mere sensual or physical gratification, unaccompanied by the suggestion of any moral emotion whatever. According to Mr Knight, however, and, indeed, to most other writers, this is the case with regard to the Beauty of Colours, which depends altogether, they say, upon the delight which the eye naturally takes in their contemplation—this delight being just as primitive and sensual as that which the palate receives from the contact of agreeable flavours.

Reasons for disputing this Doctrine.

It must be admitted, we think, in the first place, that such an allegation is in itself extremely improbable, and contrary to all analogy, and all experience of the structure of language, or of the laws of thought. It is farther to be considered, too, that if the pleasures of the senses are ever to be considered as Beautiful, those pleasures which are the most lively and important would be the most likely to usurp this denomination, and to take rank with the higher gratifications that result from the perception of Beauty. Now, it admits of no dispute, that the mere organic pleasures of the eye are far inferior to those of the palate, the touch, and indeed almost all the other senses,—none of which, however, are in any case confounded with the sense of Beauty. In the next place, it should follow, that if what affords organic pleasure to the eye be properly called Beautiful, what offends, or gives pain to it, should be called ugly. Now, excessive or dazzling light is offensive to the eye—but, considered by itself, it is never called ugly, but only painful or disagreeable. The moderate excitement of light, on the other hand, or the soothing of certain bright but temperate colours, when considered in this primary aspect, are scarcely called Beautiful, but only agreeable or refreshing. So far as the direct injury or comfort of the organ, in short, is concerned, the language which we use refers merely to physical or bodily sensation, and is not confounded with that which relates to mental emotion; and we really see no ground for supposing that there is any exception to this rule.

It is very remarkable, indeed, that the sense whose organic gratification is here supposed to constitute the feeling of Beauty, should be one, in the first place, whose direct organic gratifications are of very little force or intensity;—and, in the next place, one whose office it is, almost exclusively, to make us acquainted with the existence and properties of those external objects which are naturally interesting to our inward feelings and affections. This peculiarity makes it extremely probable, that ideas of emotion should be *associated* with the perceptions of

Beauty.

this sense, but extremely improbable, that its naked and *unassociated* sensations should in any case be classed with such emotions. If the name of Beauty were given to what directly gratifies any sense, such as that of tasting or smelling, which does *not* make us acquainted with the nature or relations of outward objects, there could be less room for such an explanation. But when it is the business of a particular sense or organ to introduce to our knowledge those objects which are naturally connected with ideas of emotion, it is easy to understand how its perceptions should be associated with these emotions, and an interest and importance thus extended to them, that belong to the intimations of no other bodily organ. But, on those very accounts, we should be prepared to suspect, that all the interest they possess is derived from this association; and to distrust the accuracy of any observations that may lead us to conclude that its mere organic impulses ever produced any thing akin to these associated emotions, or entitled to pass under their name. This caution will appear still more reasonable, when it is considered, that all the other qualities of visible objects, except only their colours, are now admitted to be perfectly indifferent in themselves, and to possess no other Beauty than they may derive from their associations with our ordinary affections. There are no *forms*, for example, even in Mr Knight's opinion, that have any intrinsic Beauty, or any power of pleasing or affecting us, except through their associations, or affinities to mental affections, either as expressive of Fitness and Utility, or as types and symbols of certain moral or intellectual qualities, in which the sources of our interest are obvious. Yet the Form of an object is as conspicuous an ingredient of its Beauty as its Colour, and a property, too, which seems at first view to be as intrinsically and independently pleasing. Why, then, should we persist in holding that colours, or combinations of colours, please from being *naturally* agreeable to the organ of sight, when it is admitted that other visible qualities, which *seem* to possess the same power of pleasing, are found, upon examination, to owe it entirely to the principle of association?

The only reason that can be assigned, or that actually exists for this distinction, is, that it has been supposed more difficult to account for the Beauty of Colours, upon the principles which have accounted for other Beauties, or to specify the particular associations by virtue of which they could acquire this quality. Now, it appears to us that there is no such difficulty; and that there is no reason whatever for holding that one colour, or combination of colours, is more pleasing than another, except upon the same grounds of association which recommend particular forms, motions, or proportions. It appears to us, that the organic pleasures of the eye are extremely few and insignificant. It is hurt, no doubt, by an excessive glare of light; and it is in some degree gratified, perhaps, by a moderate degree of it. But it is only by the quantity or intensity of the light we think that it is so affected. The colour of it, we take it, is, in all cases, absolutely indifferent. But it is the colour only that is called Beautiful or otherwise; and these qualities we think it very plainly derives from the common fountain of association.

Beauty of Colours derived from Association alone.

In the first place, we would ask, whether there is any colour that is beautiful in all situations? and, in the next place, whether there is any colour that is not beautiful in some situation? With regard to the first, take the colours that are most commonly referred to as being intrinsically beautiful—bright and soft green—clear blue—bright pink, or vermilion. The first is unquestionably beautiful in vernal woods and summer meadows;—and, we humbly conceive, is Beautiful, because it is the Natural sign and concomitant of those scenes and seasons of enjoyment. Blue, again, is beautiful in the vernal sky;—and, as we believe, for the sake of the pleasures of which such skies are prolific; and pink is beautiful on the cheeks of a young woman or the leaves of a rose, for reasons too obvious to be stated. We have associations enough, therefore, to recommend all these colours, in the situations in which they are beautiful; but, strong as these associations are, they are unable to make them universally beautiful,—or beautiful, indeed, in any other situations. Green would not be beautiful in the sky—nor blue on the cheek—nor vermilion on the grass. It may be said, indeed, that, though they are always recognised as beautiful in themselves, their obvious unfitness in such situations counteracts the effect of their Beauty, and make an opposite impression, as of something monstrous and unnatural; and that, accordingly, they are all beautiful in indifferent situations, where there is no such antagonist principle—in furniture, dress, and ornaments. Now the fact, in the first place, is not so;—these bright colours being but seldom and sparingly admitted in ornaments or works of art; and no man, for example, choosing to have a blue house, or a green ceiling, or a pink coat. But, in the second place, if the facts were admitted, we think it obvious, that the *general* Beauty of these colours would be sufficiently accounted for by the very interesting and powerful associations under which all of them are so frequently presented by the hand of Nature. The interest we take in female beauty,—in vernal delights,—in unclouded skies, —is far too lively and too constantly recurring, not to stamp a kindred interest upon the colours that are Naturally associated with such objects, and to make us regard with some affection and delight those hues that remind us of them, although we should only meet them upon a fan, or a dressing-box, the lining of a curtain, or the back of a screen. Finally, we beg leave to observe, that all bright and clear colours are naturally typical of cheerfulness and purity of mind, and are hailed as emblems of moral qualities, to which no one can be indifferent.

With regard to ugly colours again, we really are not aware of any to which that epithet can be safely applied. Dull and dingy hues are usually mentioned as in themselves the least pleasing. Yet these are the prevailing tints in many beautiful landscapes, and many admired pictures. They are also the most common colours that are chosen for dress,—for building,—for furniture,—where the consideration of Beauty is the only motive for the choice. In fact, the shaded parts of all coloured objects pass into tints of this description:—nor can we at present recollect any one colour, which we could specify as in itself disagreeable, without running counter to the

Beauty.

feelings and the practice of the great mass of mankind. If the fact, however, were otherwise, and if certain muddy and dull colours were universally allowed to be disagreeable, we should think there could be no difficulty in referring these, too, to natural associations. Darkness, and all that approaches it, is naturally associated with ideas of melancholy,—of helplessness, and danger;—and the gloomy hues that remind us of it, or seem to draw upon it, must share in the same associations. Lurid skies, too, it should be observed, and turbid waters, and unfruitful swamps, and dreary morasses, are the Natural and most common wearers of these dismal liveries. It is from these that we first become acquainted with them; and it is needless, therefore, to say, that such objects are necessarily associated with ideas of discomfort, and sadness, and danger; and that the colours that remind us of them, can scarcely fail to recal some of the same disagreeable sensations.

Beauty of Mixed or Combined Colours.

Enough, however, and more than enough, has been said about the supposed primitive and independent Beauty of separate colours. It is chiefly upon the intrinsic Beauty of their mixture or combinations that Mr Knight and his adherents have insisted;—and it is no doubt quite true, that, among painters and connoisseurs, we hear a great deal about the harmony and composition of tints, and the charms and difficulties of a judicious colouring. In all this, however, we cannot help suspecting that there is no little pedantry, and no little jargon; and that these phrases, when used without reference to the practical difficulties of the art, which must go for nothing in the present question, really mean little more than the true and natural appearance of coloured objects, seen through the same tinted or partially obscure medium that commonly constitutes the atmosphere. In nature, we know of no discordant or offensive colouring, except what may be referred to some accident or disaster that spoils the moral or sentimental expression of the scene, and disturbs the associations upon which all its Beauty, whether of forms or of hues, seems to us very plainly dependent. We are perfectly aware, that ingenious persons have been disposed to dogmatize and to speculate very confidently upon these subjects; and have had the benefit of seeing various learned treatises upon the natural *gamut* of colours, and the inherent congruity of those that are called complementary, with reference to the prismatic *spectrum*. But we confess we have no faith in any of those fancies; and believe, that, if all these colours were fairly arranged on a plain board, according to the most rigid rules of this supposed harmony, nobody, but the author of the theory, would perceive the smallest Beauty in the exhibition, or be the least offended by reversing their collocation.

We do not mean, however, to dispute, that the laws of colouring, insisted on by learned artists, will produce a more pleasing effect *upon trained judges of the art*, than a neglect of these laws; because we have little doubt that these combinations of colour are recommended by certain associations, which render them generally pleasing to persons so trained and educated;—all that we maintain is, that there are no combinations that are originally and Universally pleasing or displeasing to the eye, independent of such associations; and it seems to us an irresistible proof of this, that these laws of harmonious colouring are perpetually and deliberately violated by great multitudes of persons, who not only have the perfect use of their sight, but are actually bestowing great pains and expence in providing for its gratification, in the very act of this violation. The Dutch trader, who paints over the outside of his country-house with as many bright colours as are to be found in his tulip-bed, and garnishes his green shutters with blue facings, and his purple roof with lilac ridges,—not only sees as well as the studied colourist, who shudders at the exhibition, but actually receives as much pleasure, and as strong an impression of Beauty, from the finished *lusthaus*, as the artist does from one of his best pictures. It is impossible, then, that these combinations of colours can be *naturally* or intrinsically offensive to the organ of sight; and their Beauty or ugliness *must* depend upon the associations which different individuals may have happened to form with regard to them. We contend, however, for nothing more; and are quite willing to allow that the associations which recommend his staring tawdriness to the burgomaster, are such as could not easily have been formed in the mind of a diligent and extensive observer of nature, and that they would probably be reversed by habits of reflection and study. But the same thing, it is obvious, may be said of the notions of beauty of any other description that prevail among the rude, the inexperienced, and uninstructed;—though, in all other instances, we take it for granted, that the Beauty which *is* perceived depends altogether upon association, and in no degree on its power of giving a pleasurable impulse to the organ to which it addresses itself. If any considerable number of persons, with the perfect use of sight, actually take pleasure in certain combinations of colours,—*that* is complete proof that such combinations are not Naturally offensive to the organ of sight, and that the pleasure of such persons, exactly like that of those who disagree with them, is derived not from the sense, but from associations with its perceptions.

Effects of Light and Shadow.

With regard, again, to the effect of broken masses of light and shadow, it is proper, in the first place, to remember, that by the eye we see *colour only*; and that lights and shadows, as far as the mere organ is concerned, mean nothing but variations of tint. It is very true, no doubt, that we soon learn to refer many of those variations to light and shade, and that they thus become *signs* to us of depth, and distance, and relief. But, is not this, of itself, sufficient to refute the idea of their affording any primitive or organic pleasure? In so far as they are mere variations of tints, they may be imitated by unmeaning daubs of paint on a pallet;—in so far as they are *signs*, it is to the mind that they address themselves, and not to the organ. They are signs, too, it should be recollected, and the only signs we have, by which we can receive any correct knowledge of the existence and condition of all external objects at a distance from us, whether interesting or not interesting. Without the assistance of variety of tint, and of lights and shadows, we could never distinguish one object from another, except by the

Beauty.

touch. These appearances, therefore, are the perpetual vehicles of almost all our interesting perceptions; and are consequently associated with all the emotions we receive from visible objects. It is pleasant to see *many* things in one prospect, because some of them are probably agreeable; and it is pleasant to know the relations of those things, because the qualities or associations, by means of which they interest us, generally depend upon that knowledge. The mixture of colours and shades, however, is necessary to this enjoyment, and consequently is a sign of it, and a source of associated interest or beauty.

Opinion of Mr Knight, that the Beauty of many Pictures depends mainly on the intrinsic Beauty of their Colours.

Mr Knight, however, goes much farther than this; and maintains, that the Beauty which is so distinctly felt in many pictures of objects in themselves disagreeable, is to be ascribed entirely to the effect of the brilliant and harmonious tints, and the masses of light and shadow that may be employed in the representation. The filthy and tattered rags of a beggar, he observes, and the putrifying contents of a dunghill, may form beautiful objects in a picture; because, considered as mere objects of sight, they may often present beautiful effects of colouring and shadow; and these are preserved or heightened in the imitation, disjoined from all their offensive accompaniments. Now, if the tints and shades were the exclusive sources of our gratification, and if this gratification was diminished, instead of being heightened, by the suggestion which, however transiently, *must* still intrude itself, that they appeared in an imitation of disgusting objects, it must certainly follow, that the pleasure and the beauty would be much enhanced if there was *no imitation of any thing whatever*, and if the canvas merely presented the tints and shades, unaccompanied with the representation of any particular object. It is perfectly obvious, however, that it would be absurd to call such a collection of coloured spots a beautiful picture; and that a man would be laughed at who should hang up such a piece of stained canvas among the works of the great artists. Again, if it were really possible for any one, but a student of art, to confine the attention to the mere colouring and shadowing of any picture, there is nothing so disgusting but what might form the subject of a beautiful imitation. A piece of putrid veal, or a cancerous ulcer, or the rags that are taken from it, may display the most brilliant tints, and the finest distribution of light and shadow. Does Mr Knight, however, seriously think, that either of these experiments would succeed? Or, are there, in reality, no other qualities in the pictures in question, to which their beauty can be ascribed, but the organic effect of their colours? We humbly conceive that there are; and that far less ingenuity than his might have been able to detect them.

Refuted, 1*st*, By Facts inconsistent with it;—and,

2*dly*, By a better and more natural Explanation of the instances on which he relies.

There is, in the first place, the pleasing association of the Skill and Power of the artist,—a skill and power which we know *may* be employed to produce unmingled delight; whatever may be the character of the particular effort before us. But, in the second place, we do humbly conceive that there are many interesting associations connected with the subjects which have been represented as purely disgusting. The aspect of human wretchedness and decay is not, at all events, an *indifferent* spectacle; and, if presented to us without actual offence to our senses, or any call on our active beneficence, may excite a sympathetic emotion, which is known to be far from undelightful. Many an attractive poem has been written on the miseries of beggars; and why should painting be supposed more fastidious? Besides, it will be observed, that the beggars of the painter are generally among the most interesting of that interesting order;—either young and lovely children, whose health and gaiety, and sweet expression, form an affecting contrast with their squalid garments, and the neglect and misery to which they seem to be destined,—or old and venerable persons, mingling something of the dignity and reverence of age with the broken spirit of their condition, and seeming to reproach mankind for exposing heads so old and white to the pelting of the pitiless storm. While such pictures suggest images so pathetic, it looks almost like a wilful perversity, to ascribe their Beauty entirely to the mixture of colours which they display, and to the forgetfulness of these images. Even for the dunghill, we think it is possible to say something,—though, we confess, we have never happened to see any picture, of which that useful compound formed the peculiar subject. There is the display of the painter's art and power here also; and the dunghill is not only Useful, but is associated with many pleasing images of rustic toil and occupation, and of the simplicity, and comfort, and innocence of agricultural life. We do not know that a dunghill is at all a disagreeable object to look at, even in plain reality—provided it be so far off as not to annoy us with its odour, or to soil us with its effusions. In a picture, however, we are safe from any of these disasters; and, considering that it is usually combined, in such delineations, with other more pleasing and touching remembrancers of humble happiness and contentment, we really do not see that it was at all necessary to impute any mysterious or intrinsic Beauty to its complexion, in order to account for the satisfaction with which we can then bear to behold it.

The Beauty of Sounds all derived from Association.

Having said so much with a view to reduce to its just value, as an ingredient of Beauty, the mere organical delight which the eye is supposed to derive from colours, we really have not patience to apply the same considerations to the alleged Beauty of Sounds that are supposed to be insignificant. Beautiful Sounds, in general, we think, are Beautiful from association only,—from their resembling the natural tones of various passions and affections,—or from their being originally and most frequently presented to us in scenes or on occasions of natural interest or emotion. With regard, again, to successive or coexistent sounds, we do not, of course, mean to dispute, that there are such things as Melody and Harmony, and that most men are offended or gratified by the violation or observance of those laws upon which they depend. This, however, it should be observed, is a faculty quite *unique*, and unlike anything else in our constitution; by no means universal, as the sense of Beauty is, even in cultivated societies, and apparently withheld from whole communities of quick-eared savages and barbarians. Whether the kind of gratification, which results from the mere musical arrange-

ment of sounds, would be referred to a sense of Beauty, or would pass under that name, if it could be presented entirely detached from any associated emotions, appears to us to be exceedingly doubtful. Even with the benefit of these combinations, we do not find, that every arrangement which merely preserves inviolate the rules of composition, is considered as Beautiful; and we do not think that it would be consonant, either to the common feeling or common language of mankind, to bestow this epithet upon pieces that had no other merit. At all events, and whatever may be thought of the proper name of this singular gratification of a musical ear, it seems to be quite certain, that all that rises to the dignity of an *emotion* in the pleasure we receive from sounds, is as clearly the gift of association, as in the case of visible beauty,—of association with the passionate tones and modulations of the human voice,—with the scenes to which the interesting sounds are native,—with the poetry to which they have been married,—or even with the skill and Genius of the artist by whom they have been arranged.

eauty of immaterial objects referable to the same sources.

Hitherto we have spoken of the Beauty of external objects only. But the whole difficulty of the theory consists in its application to them. If that be once adjusted, the Beauty of immaterial objects can occasion no perplexity. Poems, and other compositions in words, are Beautiful in proportion as they are conversant with Beautiful objects—or as they suggest to us, in a more direct way, the Moral and social emotions on which the Beauty of all objects depends. Theorems and demonstrations are Beautiful, according as they excite in us emotions of admiration for the Genius and intellectual Power of their inventors, and images of the magnificent and beneficial ends to which such discoveries may be applied;—and mechanical contrivances are Beautiful when they remind us of similar Talents and ingenuity, and at the same time impress us with a more direct sense of their vast Utility to mankind, and of the great additional conveniences with which life is consequently adorned. In all cases, therefore, there is the suggestion of some interesting conception or emotion associated with a present perception, in which it is apparently confounded and embodied—and this, according to the whole of the preceding deduction, is the distinguishing characteristic of Beauty.

nsequences of s Theory, First, to ablish identity the Beautiful, the Sublime, the Picturesque.

Having now explained, as fully as we think necessary, the grounds of that opinion as to the nature of Beauty which appears to be most conformable to the truth—we have only to add a word or two as to the necessary consequences of its adoption upon several other controversies of a kindred description.

In the first place, then, we conceive that it establishes the substantial identity of the Sublime, the Beautiful, and the Picturesque; and, consequently, puts an end to all controversy that is not purely verbal, as to the difference of those several qualities. Every material object that interests, without actually hurting or gratifying our bodily feelings, must do so, according to this theory, in one and the same manner,—that is, by suggesting or recalling some emotion or affection of ourselves, or some other sentient being, and presenting, to our imagination at least, some natural object of love, pity, admiration, or awe. The interest of material objects, therefore, is always *the same;* and arises, in every case, not from any physical qualities they may possess, but from their association with some idea of emotion. But, though material objects have but one means of exciting emotion, the emotions they do excite are infinite. They are mirrors that may reflect all shades and all colours; and, in point of fact, do seldom reflect the same hues twice. No two interesting objects, perhaps, whether known by the name of Beautiful, Sublime, or Picturesque, ever produced exactly the same emotion in the beholder; and no one object, it is most probable, ever moved any two persons to the very same conceptions. As they may be associated with all the feelings and affections of which the human mind is susceptible, so they may suggest those feelings in all their variety, and, in fact, do daily excite all sorts of emotions—running through every gradation, from extreme gaiety and elevation, to the borders of horror and disgust.

Now, it is certainly true, that all the variety of emotions raised in this way, on the single basis of association, may be classed, in a rude way, under the denominations of Sublime, Beautiful, and Picturesque, according as they partake of awe, tenderness, or admiration; and we have no other objection to this nomenclature, except its extreme imperfection, and the delusions to which we know that it has given occasion. If objects that interest by their association with ideas of Power, and Danger, and Terror, are to be distinguished by the peculiar name of Sublime, why should there not be a separate name also for objects that interest by associations of Mirth and Gaiety,—another for those that please by suggestions of Softness and Melancholy,—another for such as are connected with impressions of Comfort and Tranquillity,—and another and another for those that are related to Pity, and admiration, and love, and regret, and all the other distinct emotions and affections of our nature? These are not in reality less distinguishable from each other, than from the emotions of awe and veneration that confer the title of Sublime on their representatives; and while all the former are confounded under the comprehensive appellation of Beauty, this partial attempt at distinction is only apt to mislead us into an erroneous opinion of our accuracy, and to make us believe, both that there is a greater conformity among the things that pass under the same name, and a greater difference between those that pass under different names, than is really the case. We have seen already, that the radical error of almost all preceding inquirers, has lain in supposing that every thing that passed under the name of Beautiful, must have some real and inherent quality in common with every thing else that obtained that name: And it is scarcely necessary for us to observe, that it has been almost as general an opinion, that Sublimity was not only something radically different from Beauty, but actually opposite to it; whereas the fact is, that it is far more nearly related to some sorts of Beauty, than many sorts of Beauty are to each other; and that both are founded exactly upon the same principle of suggesting some past or possible emotion of some sentient being.

Beauty.

Upon this important point, we are happy to find our opinions confirmed by the authority of Mr Stewart, who, in his Essay on the Beautiful, already referred to, has observed, not only that there appears to him to be no inconsistency or impropriety in such expressions as the *Sublime Beauties* of nature, or of the sacred Scriptures;—but has added, in express terms, that, "to oppose the Beautiful to the Sublime, or to the picturesque, strikes him as something analogous to a contrast between the Beautiful and the Comic—the Beautiful and the Tragic—the Beautiful and the Pathetic—or the Beautiful and the Romantic."

Secondly, To put an end to Disputes about the Standard of Taste.

The only other advantage which we shall specify as likely to result from the general adoption of the theory we have been endeavouring to illustrate, is, that it seems calculated to put an end to all these perplexing and vexatious questions about the Standard of Taste, which have given occasion to so much impertinent and so much elaborate discussion. If things are not Beautiful in themselves, but only as they serve to suggest interesting conceptions to the mind, then every thing which does in point of fact suggest such a conception to any individual, *is Beautiful* to that individual; and it is not only quite true that there is no room for disputing about tastes, but that all tastes are equally just and correct, in so far as each individual speaks only of his own emotions. When a man calls a thing Beautiful, however, he may indeed mean to make two very different assertions;—he may mean that it gives *him* pleasure, by suggesting to him some interesting emotion; and, in this sense, there can be no doubt that, if he merely speak truth, the thing is beautiful; and that it pleases him precisely in the same way that all other things please those to whom they appear beautiful. But if he mean farther to say that the thing possesses some quality which should make it appear Beautiful to every other person, and that it is owing to some prejudice or defect in them if it appear otherwise, then he is as unreasonable and absurd as he would think those who should attempt to convince him that he felt no emotion of Beauty.

All tastes, then, are equally just and true, in so far as concerns the individual whose taste is in question; and what a man feels distinctly to be beautiful, *is Beautiful* to him, whatever other people may think of it. All this follows clearly from the theory now in question: But it does not follow, from it, that all tastes are equally good or desirable, or that there is any difficulty in describing that which is really the best, and the most to be envied. The only use of the faculty of Taste, is to afford an innocent delight, and to aid the cultivation of a finer morality; and that man certainly will have the most delight from this faculty, who has the most numerous and the most powerful perceptions of Beauty. But, if Beauty consist in the reflection of our affections and sympathies, it is plain that *he* will always see the most Beauty whose affections are warmest and most exercised,—whose imagination is the most powerful, and who has most accustomed himself to attend to the objects by which he is surrounded. In so far as mere feeling and enjoyment are concerned, therefore, it seems evident, that the best taste must be that which belongs to the best Affections, the most active Fancy, and the most attentive habits of Observation. It will follow pretty exactly too, that all men's perceptions of Beauty will be nearly in proportion to the degree of their sensibility and social sympathies; and that those who have no affections towards sentient beings, will be just as insensible to Beauty in external objects, as he, who cannot hear the sound of his friend's voice, must be deaf to its echo.

In so far as the sense of Beauty is regarded as a mere source of enjoyment, this seems to be the only distinction that deserves to be attended to; and the only cultivation that Taste should ever receive, with a view to the gratification of the individual, should be through the indirect channel of cultivating the affections and powers of observation. If we aspire, however, to be *creators*, as well as observers of Beauty, and place any part of our happiness in ministering to the gratification of others—as artists, or poets, or authors of any sort—then, indeed, a new distinction of Tastes, and a far more laborious system of cultivation, will be necessary. A man who pursues only his own delight, will be as much charmed with objects that suggest powerful emotions in consequence of personal and accidental associations, as with those that introduce similar emotions by means of associations that are universal and indestructible. To him, all objects of the former class are really as beautiful as those of the latter—and, for his own gratification, the creation of that sort of Beauty is just as important an occupation: But if he conceive the ambition of creating beauties for the admiration of others, he must be cautious to employ only such objects as are the *natural* signs, or the *inseparable* concomitants of emotions, of which the greater part of mankind are susceptible; and his taste will *then* deserve to be called bad and false, if he obtrude upon the public, as beautiful, objects that are not likely to be associated in common minds with any interesting impressions.

For a man himself, then, there is no taste that is either bad or false; and the only difference worthy of being attended to, is that between a great deal and a very little. Some who have cold affections, sluggish imaginations, and no habits of observation, can with difficulty discern Beauty in any thing; while others, who are full of kindness and sensibility, and who have been accustomed to attend to all the objects around them, feel it almost in everything. It is no matter what other people may think of the objects of their admiration; nor ought it to be any concern of theirs that the public would be astonished or offended, if they were called upon to join in that admiration. So long as no such call is made, this anticipated discrepancy of feeling need give *them* no uneasiness; and the suspicion of it should produce no contempt in any other persons. It is a strange aberration indeed of vanity that makes us despise persons for being happy—for having sources of enjoyment in which we cannot share:—And yet this is the true account of the ridicule, which is so generally poured upon individuals who seek only to enjoy their peculiar tastes unmolested:—For, if there be any truth in the theory we have been expounding, no taste is bad for any other reason than because it is peculiar—as the objects in which it de-

lights must actually serve to suggest to the individual those common emotions and universal affections upon which the sense of Beauty is everywhere founded. The misfortune is, however, that we are apt to consider all persons who make known their peculiar relishes, and especially all who create any objects for their gratification, as in some measure dictating to the public, and setting up an idol for general adoration; and hence this intolerant interference with almost all peculiar perceptions of beauty, and the unsparing derision that pursues all deviations from acknowledged standards. This intolerance, we admit, is often provoked by something of a spirit of *proselytism* and arrogance, in those who mistake their own casual associations for natural or universal relations; and the consequence is, that mortified vanity dries up the fountain of their peculiar enjoyment, and disenchants, by a new association of general contempt or ridicule, the scenes that had been consecrated by some innocent but accidental emotion.

As all men must have some peculiar associations, all men must have some peculiar notions of beauty, and, of course, to a certain extent, a taste that the public would be entitled to consider as false or vitiated. For those who make no demands on public admiration, however, it is hard to be obliged to sacrifice this source of enjoyment; and, even for those who labour for applause, the wisest course, perhaps, if it were only practicable, would be, to have two tastes,—one to enjoy, and one to work by,—one founded upon Universal associations, according to which they finished those performances for which they challenged universal praise,—and another guided by all casual and individual associations, through which they looked fondly upon nature, and upon the objects of their secret admiration. (GG.)

BECCARIA (Cesar Bonesana, Marquis of), author of the well known treatise on *Crimes and Punishments*, was born at Milan in the year 1735. His early studies were carried on in the College of the Jesuits at Parma. He possessed a quick apprehension; but, being naturally taciturn, and inclined to reflection, he seldom communicated the progress of his ideas, and was with difficulty prevailed upon to complete his exercises. It is related, as another peculiarity of his disposition, that he never received praise from his teachers without betraying evident marks of pain and humiliation. These unusual indications of a susceptible mind, which, outstripping the course of his instructors, delighted in its own pursuits, and derived little complacency from a sense of its actual attainments, gave him, to common observers, a certain air of slowness, and even of stupidity; and characterized his features and deportment during the whole of his life. Having left the college at the age of seventeen, he applied himself, with unremitting diligence, to the study of Mathematics, and the Philosophy of Man.

His understanding appears to have been very early capable of embracing the most general views, and his breast to have been warmed by those benevolent wishes for the enlargement of human happiness, the sincerity and the strength of which are often so severely tried by the events and passions of maturer life. His propensity to the study of Jurisprudence, and Political Philosophy, was first excited or confirmed by the *Lettres Persannes* of Montesquieu; a production capable, indeed, of alluring a less enthusiastical mind than that of Beccaria. But his industry, in the pursuit of knowledge, appears to have been chiefly stimulated by the patriotic and honourable desire of diffusing instruction among his countrymen, particularly the inhabitants of Milan, whom he represents, in one of his letters, as abandoned to a state of lamentable and universal ignorance. In the prosecution of these laudable designs, he fortunately possessed the confidence, and was encouraged by the protection, of Count Firmiani, then governor of that part of the Austrian dominions; an accomplished nobleman, who, with comprehensive views of policy, concurred in every plan which was calculated for improving the state of the provinces, and the condition of their inhabitants.

Beccaria first appeared as an author in the year 1762, when he published some observations on the Derangement of the Currency in the Milanese States, and a plan for its amendment. Soon after this he established a small literary society at Milan, in concert with some associates of character and sentiments similar to his own; among others, *Alessandro* and *Pietro Verri*, who likewise contributed at that time, by their talents and public spirit, to distinguish the reign of Maria Teresa in Lombardy.* Assisted by these friends, and countenanced by Firmiani, he commenced a periodical publication under the name of the *Caffè*; a plan said to have been suggested to them by the celebrity of Addison's *Spectator*, and the general belief of its influence on the opinions and taste of the people of England. Various papers, contributed by the members of this society, on subjects of literature, ethics, and physical science, were published during the years 1764 and 1765.

But by far the most remarkable production to which this society gave rise, and that by which the reputation of Beccaria has been chiefly perpetuated among other nations, was the treatise on Crimes and Punishments (*Dei Delitti e Delle Pene*). This essay is said to have been undertaken at the earnest solicitation of Count Alexander Verri, who then discharged the functions of Protector of Prisoners (*Protettore de' Carcerati*) at the Court of Milan. It was written at the house of his brother, Peter Verri, where the meetings of the society were held; and in concert with him the author, every evening, revised

* A small publication which appeared about that time, under the title of *Thoughts on Happiness*, was written by the former. His literary pursuits were, soon after, suspended by his appointment to a public situation.

Beccaria. and corrected what he had written during the day. In this manner the work was completed within two months, and was printed in the course of the year 1764, with the mark of the Lucca press. *

In this small but noted work, the author appears as the advocate of reason and sound policy, no less than of humanity. It was his purpose, by examining the foundation, the objects, and consequently the boundaries of penal law, to expose the inefficacy, as well as injustice, of many provisions in the judicial code of his own country, and in those of other European nations; and which, derived from remote times, and established under a different order of society, had been perverted and debased during successive ages of barbarism. The authority of positive institutions formed almost the only basis of law, even in countries the farthest advanced in civilization; and that authority was in many of them drawn too servilely from the Roman system. Montesquieu had already thrown many penetrating glances at the foundation and structure of these ancient fabrics; but it was still reserved for others to scrutinize them more closely, and to draw forth, and present to general view, those direct inferences which that examination suggested. In no part were the existing codes more defective and vicious, than in the department of the criminal law; and it was to this, accordingly, that Beccaria's attention was exclusively directed. Nor does he offer the work as a general system, or theory, even of penal law; in which light it would be found every way imperfect; but only as an attempt to analyze parts of a system which he found actually existing. Among the most prominent of those points to which his reasoning is applied, are, the due proportion between crime and punishment, and the violations of that proportion, whether by unnecessary severity of punishments, or the want of a scale and distribution of them suited to the amount and danger of particular offences—the inconsistency of certain rules then established on the subject of legal Evidence—Secret Accusations—Fictitious Crimes—the use of Torture as an instrument for the discovery of truth—Imprisonment not authorized by law, or of uncertain duration—and the sale of offices of justice, along with other vices in the constitution of the courts. In treating these various topics, he seldom deduces his argument from remote sources, or pursues it to refinements. That some propositions are advanced in the course of the work, which are of a questionable nature, cannot be denied; and there are particular illustrations which have an exclusive reference to certain forms of government then existing in the Italian states. But, in general, the author reasons on few and acknowledged principles, and makes his appeal to the universal feelings of mankind. As one of the most important conclusions which result from his reasoning, or rather as concentrating a number of these conclusions, he closes his book with the following proposition:— "In order that a punishment may not be an act of violence, of one, or of many, against an individual member of society, it is essential that it should be public, prompt, and necessary, the least possible in the given case, and determined by the law." Beccaria.

His style, in this work, with exception of one or two passages, where he intentionally addresses himself only to the lesser number, is uniformly perspicuous, and, like that of all his other writings, though often eloquent, is unadorned. He employs, in some parts of it, that species of ridicule which, on a similar occasion, had been used with so great effect by Montesquieu. Thus, while treating the subject of Torture, he proposes, among others, the following query, in the form of a mathematical problem: "The force of the muscles, and the sensibility of the nerves, of an innocent person being given, it is required to find the degree of pain necessary to make him confess himself guilty of a given crime?" Peculiar traits are to be found, likewise, in other passages, of the writer's dispositions and train of sentiment. Thus having, in a later edition, modified, under that part which relates to Fraudulent Bankruptcy, some sentiments which he had originally expressed, but which, on reflection, appeared to himself too severe, he adds, in a note, "I am ashamed of what I formerly wrote on this subject. I have been accused of irreligion, without deserving it; I have been accused of disaffection to the government, and deserved it as little; I was guilty of a real attack upon the rights of humanity, and I have been reproached by nobody."

If many of the views exhibited in this work are now divested of novelty; and if, through the general adoption of them by the most cultivated nations, we are led to forget that they were once hidden, or excluded, such is the fate of all improvement, as well as of all discovery. Nor does it detract from the true character of this interesting performance, that in some enlightened countries, and in the more propitious climates of political liberty, many of the important doctrines which it inculcated were already recognised in the systems of the law. † Beccaria was among the first by whom these principles were publicly avowed, under a government in whose institutions they had no place, and over whose judicial administration they exercised no influence; and, when the age and country in which he wrote are considered, the boldness of his statements is not less to be admired than the justness of his reasoning. It is his honourable distinction, likewise, and that of

---

* These particulars, communicated in a letter of Count A. Verri to the Abbate Isidoro Bianchi, in 1802, are repeated by the latter in his *Elogio* on Pietro Verri.

† In the most favoured countries of liberty, however, the reception of some of these principles had been comparatively recent. Of others, the establishment seems even yet to be remote.

That work which has tended most to diffuse a knowledge of the progress and spirit of the English laws, viz. the *Commentaries* of Sir William Blackstone, was not published till the close of the year 1765; although his plan of delivering a public lecture on the judicial system of his country was formed in 1753. The professorship at Oxford, which gave full effect to that plan, was instituted by Mr Viner, in 1758.

Beccaria. the friends who shared his labours and his views, to have preserved, in the prosecution of those objects, an unblemished loyalty towards their prince; and, while combating, with manly perseverance, the errors which prevailed in fundamental principles of the legislation, to have abstained from all attacks which might either directly weaken the authority of the laws, or disturb the administration of the government.

According to the just exposition given by the author himself, the true tendency of such a work is not to lessen the power of the law, but to increase its influence, inasmuch as opinion has a greater command over the minds of men than force. It has frequently been repeated, indeed, that national manners must precede laws; and, in the only allowable sense of that maxim, the same might be said, perhaps, with equal truth, of opinions. But the authority of this *dictum*, and the extent to which it may be followed, are not unfrequently mistaken. An important distinction is apt to be overlooked, between those general laws, which, as they are founded in permanent principles of our nature, admit of being drawn from the first springs, but which have been disturbed by ignorance, or a barbarous policy, or the temporary dominion of some prevailing passion—and those artificial or secondary arrangements, which the circumstances and stages of political society may equally render necessary in times of knowledge, and tranquillity, and civilization. It is to the latter class only that the maxim referred to can have any just application. But it may well be questioned, whether, in any case whatever, the popular feeling and opinion should be allowed to precede, by any considerable interval, the act of the legislature. It seems, on the contrary, to be a valuable secret in legislation, and one of its most important ends, to seize the proper moment for accomplishing that union. Above all, it is expedient, in those branches of the law, which are interwoven with, and derive their support from, the moral feelings, that a legislator should seek to anticipate every better tendency of public sentiment. Through want of a well-timed interference in such cases, many advantages are relinquished, as well in the concoction and frame of the laws themselves, as in that silent influence, which a well directed system of jurisprudence carries into the opinions and habits of a community.

Of the prospects which Beccaria himself entertained as to the probable influence of his work, a judgment may be formed from the sentence of Lord Bacon, which he prefixed to some of the editions. "It is not to be expected in any difficult undertaking, of whatever kind, that the same person who sows the seed should also reap the harvest; but there must, of necessity, be a preparation, and gradual progress to maturity."

The book was received in foreign countries with avidity, and procured for its author an immediate and high reputation. "Never," says a writer in the *Biographie Universelle*, "did so small a book produce so great an effect." The medal given by the Academy of Bern was instantly bestowed upon Beccaria; and the Empress Catherine II. invited him to St Petersburgh, with the offer of an honourable station at her court; a proposal which was partly the means of procuring him a similar distinction at home. Beccaria. Of the reception which the work obtained in France, particularly among the literary societies of Paris, evidence is afforded by the correspondence of the Baron de Grimm. "This book," he writes in a letter, dated 1st August 1765, is by M. Beccaria, a Milanese gentleman, who is said by some to be an Abbé, by others a lawyer, but who, I answer for it, is one of the best heads at this moment in Europe." "You will not find in the Milanese philosopher," he elsewhere observes, "either the pitch or compass of genius which characterize the writings of the President Montesquieu; but you will discover a mind that is luminous, profound, correct, and penetrating." And he justly adds, that his is one of the few precious books *qui font penser*. It was translated into French by the Abbé Morellet in 1766; and Voltaire, soon after, published a commentary upon it, under the assumed title of *un Avocat de Besançon*. With respect to the former production, the translator took some liberties with the method and distribution of the work, which were not altogether warrantable. Voltaire's commentary is written in the light style peculiar to him; and was, evidently, intended as a vehicle for certain opinions of his own, with which the spirit and object of the original publication are entirely unconnected. But the circumstance itself sufficiently marks the impression which that publication had made, and the prominence of the views which it developed. It was rapidly translated into various other languages; its maxims became a species of current coin through a great part of Europe; and the sanction of the author's reasoning was thought not unworthy of being resorted to in British tribunals.

Although followed by many others, Beccaria's was the first work of note, in which the application of a milder and more sound system of penal jurisprudence was explicitly enforced. Nor would it be at all extravagant to refer some of the great improvements, which, from this era, were successively introduced into the written laws of different European monarchies, to the direct influence of the opinions thus generally diffused. Many such enactments, at least, were, from this time, promulgated in a tone more consonant than heretofore with the dictates of humanity and equitable rule. Of this description were, among others, not only the *urbarium*, or regulations concerning villanage, issued in 1764, by the Empress Maria Teresa, but also the more extended designs which took effect, at a somewhat later period, in the various reformed codes, published by the Empress Catherine, the Emperor Joseph II., the Grand Duke of Tuscany, and the Danish Government under the administration of the late Count Bernstorf.

At one period, a storm seemed to be preparing against the Marquis in his own country, by those who probably intended, in this form, a service to the government: but it was soon dispersed by the authority of the government itself. Beccaria had considered it his duty to communicate to Count Firmiani the offers which had been made to him by the Empress Catherine; and the intelligence was trans-

mitted by the viceroy to his own court. The conduct of Prince Kaunitz-Ritsberg, on the occasion, is highly honourable to that minister, and to his sovereign. Instead of treating the communication as a matter of no account, he makes it the subject of a long dispatch, and of repeated instructions. In one of these papers, dated 27th April 1767, after requiring particular information respecting the personal character of Beccaria, he adds, "Supposing his good qualities to preponderate, it would be desirable that the country should not lose a man whose fund of knowledge is so considerable, and who, as appears from his book, possesses a mind habituated to reflection, above all, in our present penury of thinking and philosophical men; besides that it would do little honour to the whole administration, to be anticipated by foreigners in the due estimation of talents."* Nor were these merely empty professions; but were almost immediately followed by an imperial order, for establishing, in the Palatine College at Milan, a Professorship of Public Law and Economics, under the title of *Scienze Camerali.* To this chair, expressly endowed for him, by a distinction so honourable, the Marquis was appointed on the 1st of November 1768, and commenced the duties of it in the month of January following. From the preliminary discourse (*prolusione*) which he pronounced on this occasion, and in which he briefly sets forth the objects of the institution, and some of his own leading opinions regarding them, it appears that the only instructions which he received from the regency, on his appointment, consisted in an order to deliver his discourses in the vulgar tongue; an injunction of which the motives are so honourable to that government, in common with all the circumstances attending this transaction. His lectures, which he received a special permission to deliver in his own house, attracted much notice. They were not published during his life; but have since appeared, under the title of *Elementi di Economia Pubblica*, in the compilation of the *Scrittori Classici Italiani di Economia Politica*, printed at Milan. †

As he had, in his former work, set out with stating the object of municipal law to be "the greatest happiness of the greatest number," so here the same universal principle serves him for a guide; and he assumes it as the aim of public economy "to provide, with peace and safety, things necessary and convenient for the whole community." He classes the objects of Political Economy under five heads; Agriculture, Manufactures, Commerce, Finance, and Policy; comprehending, under the latter, those laws and institutions which have a respect to the Sciences, to Education, to Police, in the modern sense of that word, and to the various means of Public Defence and Security. The design was not completed; no trace, at least, appears in the work published under the above title, relative to the subjects of Finance or Public Policy.‡ In estimating the value of these speculations, it is no less necessary, than in the case of the former work, to consider them with a reference to the state of science at the time, rather than to the present extension of knowledge in this department. Under the first three divisions, he enters at considerable length into some of the most interesting discussions which have arisen in this wide field; particularly as to the principles of public policy in regard to Agriculture, to the Commerce of Grain and Foreign Commerce generally, and to Money and Exchange. § In perspicuity of language, and distinct and patient illustration, the style of these discourses bears a considerable resemblance to that of the *Wealth of Nations;* but the coincidence between the two works, in some general and fundamental doctrines, is still more remarkable and interesting. Beccaria does not appear to have adopted the particular theory of the French Economists, which was developed about that time; although his practical doctrines on some of the most important points were conformable to the conclusions afforded by that system. ‖

Among other inferences, to which the course of his reasoning leads him, as it were by many different roads, may be noticed one, which he has himself ventured to state as a general proposition; and which marks the caution as well as enlargement of his mind, in subjects of complicated inquiry. "Every restriction on freedom," he observes, "whether in the case of Commerce, or any other, ought to be a result from the necessity of preventing an actual disorder, not the effect of a purpose or aim at amelioration." And he has repeated the same doctrine under different views, in various other passages. ¶

* The originals of these dispatches are among the state papers in the public archives of Milan.

† The editor states that this publication was made from a copy of the discourses, transcribed for the author himself, when he visited Paris in 1776.

‡ Some of the others, too, are treated rather briefly. He has, himself, defended this method of teaching by the following just and striking observations, in that part of the work where he discourses of *Interest:* "But woe to the teacher who would say all that is to be said, and leave nothing to the penetration of the learner. What is heard slips away and vanishes from the hearer's mind, unless he has an opportunity of opposing the reaction as it were, of his own intellect, to the impressions of his instructor; and more light is thrown upon a science by one process of exact reasoning which we carry on for ourselves, and it is more deeply and firmly rooted in us by that single operation, than by many and repeated trains of reasoning conducted by another."

§ Under the head of Agriculture, he proposes the scheme of an Experimental Farm to be carried on at the public expence, as a school of that science, and enters into some detail of its objects and regulations.

‖ Mirabeau's *Tableau Economique* had already appeared in the publication entitled *La Philosophie Rurale;* as well as various papers of Quesnai.

¶ For example, "The operations of Economics amount only to not permitting, and most frequently to letting alone."

Beccaria. On all these subjects, he exercises, without ostentation, the privilege of examining and judging for himself; and in doing so, although he expresses himself with plainness and energy,* he is never dogmatical. He observes this further dictate of a sound philosophy, to refrain as long as possible from any very general conclusions; and, although he appears to have disengaged his mind from the power of common and hereditary notions respecting political economy, he does not, by a transition too often made, substitute dangerous or extravagant positions in their place. He is even more distinguished by the temperate use which he makes of his liberty, than by the independence which secured him from the chain.

During the same period in which he pursued these labours, Beccaria undertook another literary task of a very different description; and commenced an *Inquiry into the Nature of Style.* † A first part of this *Inquiry* was published in 1770; but the author does not appear to have prosecuted his intention; and only one detached portion of the remainder was found among his papers. ‡ The apology which he makes for this apparent deviation from his usual objects of pursuit, drawn from a consideration of the connection subsisting between the study of the fine arts, and that of moral and political science, affords a pleasing proof of the natural expansiveness of his mind. §

His scientific and literary studies were now to be interrupted, however, by new and more flattering marks of distinction from his government. By an imperial order of the 29th April 1771, he was appointed a member of the Supreme Economic Council; on the suppression of which, he was transferred to the Magistracy of State; and, lastly, by a despatch of the 17th January 1791, was named one of the Board for Reform of the Judicial Code, civil and criminal. His activity and usefulness in the discharge of these great trusts are best proved by the circumstance, that some of the most important matters in those different departments were committed to his direction, and regulated by his counsels. The most remarkable of his state papers were, various *Ordinances* relative to the grain; a very important *Despatch* transmitted to the Court in 1771, which gave rise to the reform of the public money in 1778; a *Plan* proposed in 1780, for effecting an uniformity in the weights and measures; and certain *Proposals,* in 1786, founded on the tables of the population. His writings of this description are characterized by their method, perspicuity, and precision. It deserves to be noticed, respecting his scheme for the equalization of measures, that, of the different natural bases for exact measurement, he explicitly recommends that which may be obtained from the celestial bodies; and, in the application of it, proposes to employ the decimal method of division; being the same system which was afterwards adopted by the late Government of France. ||

In the year 1776, Beccaria made a journey to France, in company with his friend Alessandro Verri. He remained at Paris for about three weeks, which he passed chiefly in the society of D'Alembert, and other eminent men of letters; and, on his return, he visited Voltaire. This journey seems to have been the only considerable incident which, during a period of twenty-five years, diversified his manner of life, or interrupted his official duties. He died of apoplexy, in the year 1793. According to the editor of his *Elementi,* in 1804, his death was unnoticed by his country, and his tomb remained without a name.

Beccaria was twice married. He was steadfast in his friendships; modest, but tenacious of his opinions. He took pleasure in the society of literary men, and avoided that of the great. It is related of him, that the King of Naples, while at Milan, twice attempted to visit him at his house; but that the Marquis found means, on both occasions, to escape the honour intended for him by his Majesty. His exertions in the service of the public, and, above all, his earnest endeavours to promote, by every means, the cause of science, and a liberal system of education, formed the chief feature of his life. On the latter topic, he has made many forcible and eloquent appeals, in the course of his different writings; and some passages of this description, which are interspersed in his discourses of Political Economy, are not less to be admired for their intrinsic excellence, than they are interesting from the circumstances in which they were written, and the contrasts which they indirectly exhibit.

One trait of his constitutional disposition, or confirmed habit, has been recorded, as furnishing a remarkable exception to the general vigour of his intellectual character; that, notwithstanding the force with which he combated the prejudices and unreasonable apprehensions of other men, he was himself subject, when left alone, to an unconquerable timidity. We are not told whether this tendency was ascribed to early habits and a faulty education, or supposed to be the consequence of some sudden and fatal impression, which remained indissolubly associated with certain outward circumstances, or in what other manner it was formed and perpetuated. On a superficial view, it seems to denote a mind radically

* "Con un non fanatico vigore," as he has himself somewhere expressed it. But on occasions where he conceived that there might be a danger of inflaming the passions, he has claimed the tribute due to him for employing a style, "beyond the reach of the uninformed and impatient multitude."

† *Ricerche intorno alla Natura della Stile.*

‡ This additional chapter is given in the edition printed at Milan in 1809.

§ In no part of his writings is the enlargement of his comprehension, as well as soundness of his judgment, more to be remarked, than in the *Treatise* on the State of the Currency, which was his first publication, and written at the age of twenty-seven.

|| In the mathematical calculations connected with this subject, he was assisted, as he himself states, by Frisi, Professor of Mathematics at Pisa; and in the mechanical part by his brother Annibale.

Beccaria.

weak. But this is not a necessary or a just inference. The fact is, indeed, singular, and deeply impressive; but, in truth, it only serves as a new example to prove how mixed is the nature of our frame; how imperfectly the understanding acts upon the will, and the will upon the mortal part; how many things appear to be within the jurisdiction of our reason, which, nevertheless, are superior to its control.

This is not the place to engage in a more particular examination of the spirit and scope of Beccaria's writings. He is said to have expressed, at least during the early part of his life, too unqualified an approbation of the works of Helvetius, and others belonging to the same school of philosophy. On this score, some excuse may, perhaps, be found for him in the attractions which the style of the author now mentioned possesses for a youthful and ardent mind. It is to be observed, likewise, that, when he expressed this admiration for the productions alluded to, the *Systême de la Nature* had not yet made its appearance. Nor is it to be supposed that he could be insensible to the notice, and the applause, of such men as then held the stations of greatest eminence in the scientific world. Yet, whatever temptations he may have been exposed to from the influence of some of his literary associates, it is consolatory to reflect, that, neither in the works which he himself gave to the public, nor in those which have been brought to light since his death, are sentiments to be found which have a tendency to subvert any one foundation of private or of public good. His labours were beneficent, and their natural fruits, the dissemination of useful knowledge, the increase of industry, and the improvement of social order. But he was not to witness the spectacle which ensued, or to be an observer of that moral crisis, of the results of which it may be questioned, if, hitherto, they have less disturbed the calculations of the friends of humanity, than baffled the counsels of its foes.

Some farther information, with respect to Beccaria's publications, will be found in the *Notizie*, prefixed to his *Economia Pubblica (Scrittori Classici Italiani*, Tom. XI.); in the 4th volume of the *Biographie Universelle*, printed at Paris in 1811, and in the 4th and 5th volumes of the *Correspondance par le Baron de Grimm*. In the compilation first mentioned are contained (besides his *Elementi*), republications of his *Relazione della Riduzione delle Misure di lunghezza all' Uniformità, per lo stato di Milano;* of his *Prolusione letta nell' apertura della nuovo cattedra de scienze camerali;* and of his inquiry *Del Disordine e De' Rimedi delle Monete*. In the same collection is likewise to be found a paper written by him for the periodical work called *Il Caffè;* viz. *Tentativo Analitico sui Contrabbandi*, being an attempt to apply the algebraical method to certain subjects of political economy. A new edition of Morellet's French translation of the *Treatise on Crimes and Punishments* was published by M. Roederer in 1797; and a version of the same treatise into modern Greek, by Coray, was published at Paris in 1802. (EE.)

BECCARIA (GIAMBATTISTA), a very ingenious and industrious electrician and practical astronomer, was born at Mendovi, the 2d of October 1716, and entered the religious order of the Pious Schools in 1732. He became a professor of experimental physics, first at Palermo, and then at Rome, and was appointed to the same situation at Turin in 1748: he was afterwards made tutor to the young Princes de Chablais and de Carignan, and continued to reside principally at Turin for the remainder of his life. In May 1755, he was elected a Fellow of the Royal Society of London, to which he afterwards communicated several papers, relating to his favourite pursuits. He died 27th May 1781.

1. The most voluminous and most important of his works, entitled *Dell' Elettricismo Artificiale e Naturali*, appeared at Turin, 1753, 4to; and was reprinted in 1772. It was translated into English, and published, with the original engravings, under the title of *A Treatise upon Artificial Electricity, and an Essay on the Mild and Slow Electricity of the Atmosphere*. 4. Lond. 1771.

2. *Risposta ad una Lettera intorno al suo Elettricismo*. 4. Milan, 1753.

3. *Lettere dell' Elettricismo Atmosferico Ed.* 2. 4. Turin, 1758.

4. *Experimenta et Observationes quibus Electricitas vindex late constituitur atque explicatur*. 4. Graz.

The accurate and elaborate experiments, related in these works, have obtained for their author the warm and repeated encomiums of the scientific historian Dr Priestley, and the approbation and friendship of other contemporary philosophers; although it must be confessed, that amidst the multitude of important facts recorded in them, we sometimes observe a want of clearness of arrangement and closeness of reasoning; nor must we attempt to claim for Beccaria either the originality of a Franklin, the mathematical precision of an Æpinus, the enlarged views of a Cavendish, or the neatness and inventive talent of a Volta. The most remarkable novelties, which deserve to be distinguished among our author's experiments and opinions, relate to the limited conducting power of water, to the electrification of the air and smoke, to the velocity of electricity, to the reduction of metals by its powers, to the illumination of the solar phosphori by the spark, to the light excited by the motion of the air, and to a variety of meteorological phenomena, especially lightning, storms, rain, waterspouts, and atmospherical magnetism. The resistance exhibited by water to the passage of the electric fluid is demonstrated by the luminous appearance of its path, while it passes through more perfect conductors without producing light; as well as by the explosion of glass tubes containing water, through which the spark is taken; and this experiment is extended to the construction of an electrical water gun, which is said to have carried a small bullet with considerable force.

Father Beccaria observed, about the same time with Mr Canton, that the air surrounding an electrified body was capable of becoming electric by slow degrees, and that it also parted slowly with its electricity; and, by means of some property of this kind, he produced the appearance of a luminous atmosphere about an electrified ball, to which another was presented, in a partial vacuum. The smoke of

Beccaria.

colophony, surrounding an electrified body, enabled it to give longer sparks, but this smoke was little attracted by the body when the heated spoon containing the colophony was insulated. Respecting the velocity of electricity, he relates some experiments, which amply deserve to be confirmed or confuted. He found the effect of a spark occupy at least half a second in passing through 500 feet of wire, and 6½ through a hempen cord of the same length, although, when the cord was wetted, it passed through it in 2 or 3 seconds. It is well known, that, in the earlier experiments of Watson, a shock was transmitted through a much longer circuit of wire, without occupying any perceptible interval of time in its passage. Many of the metals were revived from their oxyds, and mercury was reproduced from cinnabar by the powers of electricity; and our author fancied that he had discovered a common principle in the different metals, as several of them gave the same colour to the surface of the glass to which they were attached. The brilliancy of the electric light was demonstrated by the permanency of its effect on the solar phosphori; and this subject was afterwards pursued by various experiments of Canton, and others. The light often exhibited by the air rushing into a vacuum, is attributed by Beccaria to the friction of the air against the sides of the glass. It may be remarked, that the phenomenon is, in all probability, of the same kind as the appearance of light observed long ago in the air-gun by its first inventor, Ctesibius of Alexandria. With respect to atmospherical electricity, Beccaria's researches were most laborious and extensive, and he made a great variety of experiments illustrative of the nature of lightning, and of storms in general; showing, for instance, the facility with which small bodies are forced into the course of the electric current, as light clouds are made to assist in conveying a stroke of lightning, and proving that evaporation, and the deposition of vapour, are always accompanied by electrical changes. Thunder-storms, in general, he attributes to terrestrial electricity, and supposes the clouds to be merely the channels by which the fluid is carried from one part of the earth's surface to another, the equilibrium having been first disturbed by chemical changes within the earth; and it must be confessed, that this opinion is, in some measure, encouraged by the frequent connection which is observable between these phenomena, and those of earthquakes and volcanic eruptions. Water-spouts, he assures us, on the authority of several eye-witnesses, may certainly be dispersed by pointing swords and knives at them; and, with respect to conductors erected for safety, though he appreciates their utility very highly, he thinks that every large building should be furnished with more than one or two. The *electricitas vindex*, so often mentioned, is the electricity made sensible in one body by the removal of another which has been situated near it,—a property which afterwards led to the elegant inventions of the electrophorus and the condenser of Wilke and Volta. Our author appears to be somewhat disposed to exaggerate the importance of electrical changes as the causes of other atmospherical phenomena, and, in particular, to overrate the intimacy of the connection of electricity with magnetism. The appearance of the *aurora borealis* he attributes to the circulation of electricity through the higher regions of the atmosphere, and he was well aware of the magnetical changes which usually accompany this remarkable occurrence.

5. His papers in the *Philosophical Transactions* are all in Latin. The first is entitled, *Experiments in Electricity, in a Letter to Dr Franklin.* (*Ph. Tr.* 1760, p. 514.) These experiments relate principally to the subject of electrical attractions and repulsions, which the author attempts to reduce to the effect of currents of air displaced by the immediate action of the electric fluid. He supposes the air between two bodies, in dissimilar states, to be rarefied by the interchange of their electricity, so as to produce the appearance of attraction; and when the bodies are in similar states, he imagines the air interposed to be the immediate object of their apparently mutual repulsion. The paper is accompanied by a note of Dr Franklin, explanatory of the apparatus employed.

6. *An Account of the double Refractions in Crystals.* (*Phil. Trans.* 1762, p. 486.) The double refraction of rock-crystal had been observed by Huygens. Beccaria seems to have imagined, that it was not discoverable when the surfaces concerned were parallel to each other; but later observations have shown, that his observations were defective in this respect, at the same time that they have confirmed his conjecture respecting the existence of a similar property in almost all crystallized substances.

7. *Novorum quorundam in re Electrica Experimentorum Specimen.* (*Phil. Trans.* 1766, p. 105.) In this paper, our author defends the simpler theory of Franklin against Mr Symmer's doctrine of the existence of two separate electric fluids. He also enumerates a great variety of cases of the excitement of positive or negative electricity by the friction of different substances with glass, hareskin, a silk stocking, sealing-wax, and sulphur.

8. A second paper, with the same title, appeared in the *Philosophical Transactions* for 1767, p. 297. It contains an account of a repetition of experiments on the modification produced in the charge of two or more glass plates, by separating them, and by removing and replacing their coatings. These investigations were principally suggested by the well-known observations of the Jesuits, made at Pekin many years before, and by some subsequent experiments of Mr Symmer. The author calls the effect an oscillation of electricity; it depends on the same causes as the "vindicating electricity," which he has elsewhere described.

9. *De Atmosphæra Electrica libellus.* (*Philosophical Transactions*, 1770, p. 277.) The phenomena of induced electricity are here discussed, but not with great precision; the author adverts, however, to the Newtonian demonstration of the equilibrium of the force of a gravitating substance, distributed through the surface of a sphere, with respect to a particle within it, and gives somewhat clearer views of the theory of electricity than his former works had exhibited, but still falls far short of the perfection which Æpinus had attained more than ten years before.

10. A short *Letter to Mr John Canton, on his new*

Beccaria ‖ Beckmann.

phosphorus receiving several colours, and only emitting the same, is printed in the *Philosophical Transactions* for 1771, p. 212. Our author admitted the sun's light through green, red, and yellow glass, and found that the pieces of sulfureted lime exposed to it, emitted only a light similar to that which had been thrown on them. A multiplicity of later experiments have however shown, that the contrary result is by far the most common; and Zannotti's earlier observations have been fully confirmed by Wilson, Grosser, and Seebeck.

11. In 1759, Beccaria received orders from his sovereign, in consequence of a suggestion of Boscovich, to measure the length of a degree of the meridian in the immediate neighbourhood of Turin; the measurement was completed in 1768, and an account of it was published under the title of *Gradus Taurinensis,* 4. Turin, 1774; prefaced by a proper compliment to the memory of the monarch who patronised the undertaking, and to the virtues of his successors, under whose auspices it was completed. The result did not, however, exhibit the appearance of any great accuracy or good fortune, for there is not only a difference of one-seventieth of the whole in the lengths of the degree computed from the northern and southern portions of the arc, of 27′ and 41′ respectively, but the length deduced from the whole arc, which is 57468.59 French toises, is 445 toises more than would be inferred from other measurements in the neighbouring latitudes: hence it appears to have been thought necessary by later astronomers to reject the northern portion altogether, and to make some corrections in the calculation from the southern, by which the length of the degree has been reduced to 57069 toises. The Zenith sector employed for the observations was made on Boscovich's construction, the length of the tangent being measured instead of that of the arc, a method by no means calculated to lessen the chances of error. A portable syphon barometer is also described, by means of which the elevations were ascertained; and a number of heights of places in the mountains of Piedmont are recorded.

12. This volume appears to have been the last of Beccaria's publications: An *Essay on Storms and Tempests* is mentioned, without approbation, in the *Dictionnaire Historique*, but it was probably extracted from some of his other works. In his private history and adventures there appears to have been little for a biographer to relate; his ambition having been in great measure limited, by the religious profession which he had adopted, to the acquirement of literary celebrity, his taste was guided by his prevailing pursuits. His only luxuries consisted in his library and instruments; and on these he expended a considerable part of the remuneration which he received, as a recompense for his services to the public, and to his royal pupils. (A. M.)

BECKMANN (John), during nearly forty-five years Professor at Göttingen, was born at Hoye, in the electorate of Hanover, in 1739. His father, who was receiver of taxes, and postmaster in this town, occupied himself in the cultivation of a small piece of land, and appears to have inspired his son with a taste for agriculture. However, all the honour of his education belongs to his mother, who, having become a widow when young Beckmann was hardly seven years old, sent him, in his fifteenth year, to the school at Stade, placing him under the care of Gehlen. Being intended for the clerical function, he repaired in 1759 to Göttingen, to finish his studies there; but whether the advice of Hollmann, who testified much kindness towards him, produced a change in his plans; or that the instructions of the mathematicians, Kaestner and Tobias Mayer, had greater attractions for him than theology, he abandoned the career on which he had entered, in order to devote himself entirely to the natural sciences, and principally to the application of these sciences to economical purposes. His first studies were not without their use to him; he derived from them a methodical habit of mind, and a considerable knowledge of languages, which, in the sequel, assisted him greatly in the pursuits to which he owed his celebrity. In 1762, having lost his mother, and with her his former means of subsistence, he accepted the offer of Busching, who invited him to come and fill the situation of Professor of Natural Philosophy in the Lutheran Academy at St Petersburgh, of which this celebrated geographer had at that time the direction; but Busching quitting the institution shortly after, and dissensions having arisen among the superintendents, Beckmann gave up his place, and made a journey through Sweden to acquire a detailed knowledge of the mines of this country, and of the manner of working them. Linnæus having received him hospitably at Upsal, he prolonged his stay there, and availed himself of the friendship as well as the instructions of this naturalist. In 1766, the governors of the University of Göttingen appointed him, on the recommendation of Busching, Professor to this celebrated establishment, of which he became one of the principal ornaments. His mind, entirely directed to the practical uses of human knowledge, had early conceived the idea of an academical classification of the arts and different branches of economy, both political and domestic, which had hitherto been left to routine and accident. He composed, to serve him as a guide in this course of instruction, *Treatises on Rural Economy—On Policy—On Finance—On Commerce,* and other departments of practical knowledge; which, though since carried to a higher degree of perfection, owed to Beckmann their first elements, and their first scientific form. His *Lectures,* which had at the time the recommendation of novelty, were attended by the flower of the studious youth, whom the most civilized nations of Europe sent to the University of Göttingen; and it may be added, that the most distinguished statesmen and public functionaries of Germany were among his auditors. He was in the habit of accompanying them himself into the workshops, to give them a knowledge of the different processes and handicrafts, of which he had explained to them the theory. He never relinquished his public lectures; but his private studies took insensibly a direction altogether historical, the motives for which it will not be uninteresting to point out.

It is considered at Göttingen, that a Professor

Beckmann.

ckmann. cannot be excused from explaining the progress of the science, which he teaches, in all the civilized nations of Europe at the same time. Any one, who, two years after the appearance of a work of importance in his department, published in any country of Europe whatsoever, should not have read and analyzed it in order to refute or else enrich his own observations from it, would not regard himself as a worthy successor to the chair of Haller, of Mosheim, of Gessner, and Michaelis. Beckmann in particular, having studied at Göttingen at a time when the example of these great men dictated the law and gave the tone there, was determined to advance in a line with his age, and not to be ignorant of any of the steps which were making by the numerous and extensive sciences which furnished the foundation and the subjects of these practical principles. But these steps were the steps of a giant; and whatever might be his ardour, or his love of study, how could he be supposed to read and judge of all the important works which appeared from the year 1770, on chemistry theoretical and practical, on physics, natural history, and mathematics? His disappointment ended in chagrin, and gave him a degree of anger against the new ideas, methods of reasoning, and materials, which changed the face, enlarged the limits, and facilitated the study of these sciences. His course of lectures, turning only on practical matters, suffered little from this circumstance; but feeling that his writings would be accused of remaining behind the progress of the sciences which were the subject of them, he directed the researches with which he wished to occupy the attention of the public to the history of arts and trades, and employed, in the illustration of this subject, the materials to which he had access in the Göttingen library, assisted by general information, a mind peculiarly fitted for this kind of study, and by indefatigable industry. It is to these labours that we owe the *Notices* of Beckmann on the history of discoveries in the most common arts of life; for instance, the history of watch-making, of distillation, of almanacs, of insurance, of the lighting of streets, of the original country and migrations of the fruits and flowers in our gardens, of the common materials for dyeing, of bellows, of fire-arms, of mills, of grinding corn, of carriages, of different parts of our dress, of different household utensils, of a multitude of machines and mechanical contrivances employed in common trades, and of most of the products of industry; such as the gathering of saffron, the preparation of alum, the printing-press, of fulling-mills, of book-keeping, of the digging of turf, of gazettes and newspapers, of stamped paper, of the pearl-fishery, of pavings, of chimneys, of collections of natural curiosities, of milestones, of pharmacy, of quarantine, of painted paper, of ruffles, of milking, of pawn-brokers, of looking-glasses and glass in general, of soap, of musical-glasses, of watchmen, of ices to eat, of the anatomy of plants, of exchange, of pens for writing, of instruments of husbandry, of fireworks, of the working of pewter, of the procuring of amber, of indigo, of gilding, of weathercocks, of furs, of steel, of gardening, of crayons, of knives and forks, of corks, of sal-ammoniac, of hops, of weaving, of lotteries, of hospitals for orphans and foundlings, of infirmaries, of lazarettoes, of fighting-cocks, of saltpetre, of gunpowder, and aquafortis, &c. &c. We should form to ourselves a very false idea of these *Notices*, if we expected to find in them only some general account of these arts, and of the different manner of practising them, used in different times and places. Beckmann traces their first germ from the most remote periods of antiquity; he follows their developement through the obscurity of the middle ages; and exhibits their latest improvements amongst the civilized nations of modern Europe, with a patience and a depth of learning which can only be equalled by the sagacity and the variety of knowledge displayed in his researches. We have thought it would be interesting to the reader to see a list of the most remarkable among these notices, in the order in which they were published. They make five volumes in octavo, published at Leipsic from 1783 to 1805; and will furnish the most invaluable materials to the individual, or to any society of men of letters who may hereafter venture to undertake the general history of the origin and progress of the mechanic arts, which are so important a branch in that of civilization. It is almost needless to add, that the most exact references to original authorities accompany each article, and give it a new value in the eyes of those who are unwilling to take things upon trust, or may be desirous to push the inquiries of the author still farther. Beckmann.

The same merits belong to his *History of the earliest Voyages made in modern times*; a highly interesting collection, which occupied the last years of his life, and which he left at the eighth number. Another result of the literary application of the industry of Beckmann was a return to the studies of humanity, to which we are indebted for editions of the work *De Mirabilibus Auscultationibus*, attributed to Aristotle (1786); of the *Wonderful Histories* of Antigonus Carystius (1791); and of Marbodius's *Treatise on Stones* (1799);—editions which required the rare union of physical knowledge and sagacity with philological learning. The Royal Society of Göttingen had, in the year 1772, admitted him one of its members, and, from that period to 1783, Beckmann supplied their proceedings with interesting memoirs, among which are the following: *On the Reduction of Fossils to their Original Substances.—On the History of Alum.—On the Sap of Madder.—On the Froth of the Sea, from which the Heads are formed for the Nicotian Fistulæ.—On the History of Sugar.** But, from this period, he desisted all at once from partaking the labours of this learned body, probably from the same motives that we have assigned above for the change in the objects of his own particular studies. He was, besides, modest to an extreme degree; and his natural timidity did not find any thing to counteract it in the traditional jealousy of reputation, which the example of

* See *Novi Commentarii Soc. Sc. G.* Tom. II.—VIII. and *Commentar.* Tom. I.—V.

his predecessors, who had founded the glory of Göttingen, had transmitted to a generation more confident of its powers, and more vain of its merit, but still restrained by habits difficult to lay aside, when the respect for great authorities had originally sanctioned them. His candour, his sincerity, his fidelity in friendship, his affability to his scholars, have been celebrated with one accord by his coadjutors and his auditors. Schlætzer, whom he had known from his youth in Russia, was the one among his colleagues with whom he maintained the most uninterrupted intimacy. He was better qualified than almost any one else, to appreciate the researches of Beckmann, as he had himself insisted with so much force on the necessity of introducing into history a view of the influence exercised on social institutions by the efforts of industry, and by the birth or maturity of the most common arts. Beckmann died the 3d of February 1811, after having been admitted into almost all the learned societies of Germany and the north, and after having impressed a tendency to pursuits of practical utility on the minds of a multitude of distinguished young men who had attended his lectures, and whom his celebrity drew to Göttingen during the forty-five years of his professorship. A portrait of him will be found at the head of the twelfth volume of the *Economical Encyclopedia* of Krunitz, and it has been engraved separately by Raid, Schwenterley, and Grape. Beckmann married the daughter of Hollmann, his tutor and friend; she survived him only a few weeks, and they left a son and daughter grown up. His eulogium was pronounced by his colleague, the illustrious Heyne, and was published at Göttingen, with this title: *Memoria Joan. Beckmann, Soc. R. Sci. Götting. sodalis in concessu Soc. Publico D.* 16 *Febr.* 1811, *commendata.* (z.)

BEDDOES (Thomas), a physician of great eminence for his talents and philanthropy, was born at Shiffnall in Shropshire, on the 13th of April 1760, and was originally of Welsh extraction. He received the first rudiments of his education at a school in his native town, and afterwards at a seminary at Brood in Staffordshire. The strength of his intellectual powers was apparent at a very early period of his life: and he was remarkable from his infancy for his insatiable thirst for books, and for his indifference to the common objects of amusement, which usually captivate the attention of children. His rising abilities were discerned and justly appreciated by his grandfather; a man of great natural acuteness of mind, and who, by his industry and enterprise in trade, had acquired a considerable fortune. To this intelligent relation he was deeply indebted for many of the advantages of his early education, and for prevailing on his father (who, wishing to retain his son beneath the paternal roof, and train him up to business, was less anxious about his literary acquirements) to fix his destination for one of the learned professions. When he was only nine years old, the circumstance of an accident which befel his benefactor, and which, after being followed by some remarkable symptoms, terminated fatally, was calculated to make a deep and lasting impression on a mind like that of young Beddoes, and was sufficient to give it a decided direction. By the extraordinary acuteness and interest which he manifested on this occasion, he attracted the notice of Mr Yonge, the surgeon who attended the sufferer; and a foundation was thus laid for the friendship which ever after subsisted between them, and which appears to have had a considerable influence in his choice of that profession, in which he was destined to run so brilliant a career. Under the tuition of the Reverend Mr Harding, at the Free Grammar School in Bridgnorth, he made rapid progress in classical learning; and was distinguished by his great fondness for reading, by his facility in acquiring knowledge, and by the possession of a memory surprisingly retentive, a faculty which he retained through life. When about thirteen years of age, he was placed as a pupil with the Reverend Mr Dickenson, Rector of Plymhill in Staffordshire, with whom he continued about two years, and who has given the following report of the zeal with which he pursued his studies. "During the period that Dr Beddoes was under my care," observes Mr Dickenson, "his mind was so intent upon literary pursuits, chiefly the attainment of classical learning, that I do not recollect his having devoted a single day, or even an hour, to diversions or frivolous amusements of any kind. His vacant hours were generally employed in reading Reviews, of which he had access to a very numerous collection." It is singular, that, in giving a sketch of his mental powers, though he describes his judgment as solid, he represents his genius as not "enlivened by any remarkable brilliance of fancy." We shall soon have occasion to observe how eminently he was afterwards gifted with the very quality, in which a near observer of his character pronounced him to have been at that time deficient. His moral conduct was ever irreproachable, and his docility and equanimity of temper were in the highest degree exemplary.

He continued the same habits of sedulous application, and retained the same independence and integrity of character at the university, to which he was removed on quitting Mr Dickenson. He entered at Pembroke College, Oxford, in Michaelmas term 1776. The simplicity of his appearance, and the rusticity of his manners and address, could not long conceal the superiority of his mental powers, which became more conspicuous by extended competition, and soon met with the respect and applause to which they had so high a claim. The themes and declamations of young Beddoes were remarkable for their elegant latinity; and he soon acquired distinguished reputation as a classical scholar. Success in one acquisition was to him but an inducement to the possession of another; and already versed in the ancient, he resolved to become master also of the modern languages. He was found one morning by a friend, who casually entered his apartment, very busily engaged with a French grammar and dictionary before him. On his inquiring what was the nature of his studies, Beddoes told him that he was only learning French. His friend expressed surprise that he should attempt it without a master. He replied, that it was unnecessary, and that he should conquer the difficulties of the language by himself in about two months. His friend

 desisted from farther interference; but, noting in his own mind the date of his visit, called upon him again at the expiration of two months, and taking the opportunity of turning the conversation to the subject, inquired whether he had mastered the language. Beddoes answered in the affirmative, and proved his assertion by reading in English, with perfect fluency, and much to the astonishment of the hearer, a French book which the latter presented to him. From the French he proceeded to the Italian, which, from its analogy with the former, he acquired with great ease. The German language presented more serious difficulties; but his perseverance triumphed over them without the aid of any master. Not content with this, he afterwards added the Spanish language to his other acquisitions, as if determined to possess every avenue, by which useful or ornamental knowledge could possibly be attained.

Whatever time he may have devoted to general literature, while at the University, chemistry and the other sciences more closely connected with his future profession, were always his favourite objects of pursuit. The splendid discoveries of Black and Priestley, which had opened a new field of discovery, and promised to lead to the most important results, were powerfully calculated to inflame the ardour of so inquisitive and sanguine a spirit as that of Beddoes; and he accordingly soon became perfectly conversant with the new doctrines of pneumatic chemistry, and used to exhibit, with great delight, the experiments which supported them, to a circle of literary friends in Shropshire, during his vacations. He was also much occupied with mineralogy and botany; and for the former of these sciences, especially, retained throughout life a remarkable fondness.

Having taken his Bachelor's degree at one and twenty, he repaired to London, in order to commence the study of his profession, for which, as is well known, the English Universities do not provide the means. He became a pupil of the celebrated Sheldon, and devoted his time to the details of practical anatomy, and the physiological inquiries connected with it. It was while he was engaged in these studies, that he gave to the world, in 1784, a translation, from the Italian, of Spallanzani's *Dissertations on Natural History*; a work which, in the year 1790, went through a second edition. In the year following (1785), he published a translation of Bergman's *Essays on Elective Attractions* (the first work to which Beddoes affixed his name), accompanied by numerous original notes, which display an accurate acquaintance with all the modern improvements in the physical sciences. In 1786, he became again known to the public as the editor of Scheele's *Chemical Essays*. Previously to this, in 1783, he took his degree of Master of Arts; and, in the autumn of 1784, removed to Edinburgh, where he remained during three successive winters, and one summer. Shortly after his arrival, he became a member of the Medical Society, and of the Natural History Society of that place, and took an active part in the series of physiological experiments, in which some of the members of the former were, at that period, engaged: to the latter he contributed two papers, one on the *Sexual System of Linnæus*, the other on the *Scale of Being*, both of which have been preserved at full length in Dr Stock's Memoirs of his life. The high estimation in which his talents were held at Edinburgh was shown, not only by his receiving every mark of honourable distinction from his fellow students, which it was in their power to confer, but also by their choosing him as the organ of their remonstrances with the Managers of the Infirmary, on the occasion of a misunderstanding which had arisen between them, as to the hours at which they should be permitted to attend; and they were eminently indebted to him for the firmness with which he, on that occasion, maintained their privileges.

After taking his degree of Doctor in Medicine at Oxford, in December 1786, he made, in the ensuing summer, an excursion into the Highlands, and also spent a short time at Paris and Dijon, where he cultivated the acquaintance of Lavoisier and Guyton de Morveau. Soon after his return, he was appointed to succeed Dr Austin, in the Chemical Lectureship at Oxford, an office which he was eminently qualified to fill. The success which attended his exertions to inspire a taste for scientific researches was soon apparent, in the full and generally overflowing audience attracted by his lectures, and by his communicating to most of his hearers a large portion of that enthusiasm for the pursuit of which he was himself possessed. Enjoying the reputation of distinguished talents, in a place where so much deference is paid by all ranks to the possessor of so noble a distinction, and surrounded by men of learning and abilities, who courted his society, his situation at the University appears to have been truly enviable; and it is difficult to understand the motives which could have led him to relinquish all these advantages, for the uncertain prospects afforded by his establishing himself in any other town. The decided part which he took in the political discussions that were agitated at the beginning of the French Revolution, seems to have had a principal share in this determination. His opinions, which it was no part of his character ever to conceal within his own breast, were, on this occasion, expressed with his usual freedom; and were of a nature to give offence to many of his former admirers; and the circulation of a political article which he inserted in a Shropshire paper, in reply to some misrepresentations which had previously been made, in an advertisement soliciting relief for the French emigrant clergy, excited a clamour against him, which accelerated his adoption of the step he had previously determined upon, that of resigning his Lectureship, and quitting Oxford.

During his connection with the University, he published, at the Clarendon press, in 1790, an analytical account of the writings of Mayow, under the title of *Chemical Experiments and Opinions, extracted from a Work published in the last Century*; in which he asserts the claims of that extraordinary man to the discovery of the principal facts on which the modern system of pneumatic chemistry is founded; discoveries which Mayow had achieved at a very early period of life, and which had failed, for upwards of a century, to attract any notice from

the philosophic world. In the *Philosophical Transactions* for 1791 and 1792, we also find three papers by Dr Beddoes, the one containing *Observations on the Affinity between Basaltes and Granite*, in which he rejects the common division of mountains into primary and secondary, and states some strong arguments in favour of the volcanic origin of both; the other giving *An Account of some Appearances attending the Conversion of Cast into Malleable Iron*, which he supposes to consist in its purification from oxygen, charcoal, and hydrogen, which escape, during the process, in the form of carbonic acid and carburetted hydrogen gases; and, in a paper which forms an appendix to the latter, he relates a variety of experiments which he had made, confirming this theory.

The uncertainty of his future destination, on his retiring from Oxford, does not appear to have interrupted his literary labours; for it was at this period that he published his *Observations on the Nature of Demonstrative Evidence, with an Explanation of Certain Difficulties occurring in the Elements of Geometry, and Reflections on Language*, 8vo, London, 1793. In this essay he contends, in opposition to the doctrines of the ontologists, and particularly to that of Mr Harris, the author of *Hermes*, that geometry is essentially founded in experiment; and that mathematical reasoning proceeds, at every step, upon the evidence of the senses; or, in other words, that this science is a science of experiment and observation, founded solely upon the induction of particular facts; as much so as mechanics, astronomy, optics, or chemistry. He endeavours to show that Euclid sets out from experiment, and appeals constantly to what we have already learned, or may immediately learn from the exercise of our senses. This paradox he attempts to support by a sophistical analysis of one of the elementary theorems in the first book of Euclid, and of the leading definitions and axioms prefixed to it. He is afterwards led to consider the origin of abstract terms, and the philosophy of language; and adopts on these subjects the views which have been presented by Mr Horne Tooke in his Επεα Πτεροεντα; whose speculations, together with those of Lord Monboddo, Schultens, Hemsterhuis, and other Dutch etymologists, he severally reviews and criticises in an appendix of some length.

About the same period he published a work entitled *Observations on the Nature and Cure of Calculus, Sea-Scurvy, Consumption, Catarrh, and Fever; together with Conjectures upon several other Objects of Physiology and Pathology*. He there recommends, as a cheap and commodious remedy for calculus, the exsiccated carbonate of soda, made into pills with an equal weight of soap; in proof of the efficacy of which, he adduces a number of interesting cases. He then proceeds to develope his favourite pathological theories on the diseases which destroy so large a proportion of the human species; theories on which he afterwards built so many specious, but unfortunately abortive projects for their cure. Sea-scurvy and pulmonary consumption he conceived to arise from opposite chemical conditions of the body; the former consisting in a gradual abstraction, the latter in a gradual accumulation of oxygen in the system. He supports these opinions by a variety of ingenious and plausible arguments; and proposes submitting them to the test of experiment, by administering to consumptive patients such gases as may contain a smaller proportion of oxygen than is contained in common atmospheric air. The new views of pathology which these speculations presented, and the hopes of valuable practical results which they raised, excited great attention in the medical world, and contributed much to increase the reputation of their author.

On leaving Oxford, he retired to the house of his friend Mr Reynolds of Ketley in Shropshire. It was here that he published his admirable *History of Isaac Jenkins*; a story intended to impress the most useful of moral lessons on the labouring classes, by exhibiting the reformation of a drunkard, and his return to habits of sobriety and industry. The execution of this work is worthy of the design. There is, probably, none of Dr Beddoes's productions which unites so many peculiar excellencies as this inimitable fiction, or which displays at once, in so favourable a light, the vigour of his genius, his deep knowledge of the human heart, and the power with which he could command the interest and sympathy of his reader. No work of its kind has ever had the same success; repeated editions, amounting to above forty thousand copies, were rapidly sold; and a large impression has since been issued at the request of a Society for promoting knowledge by the distribution of useful popular books.

A prospect now opened to him of realizing a scheme to which his wishes had for a long time been ardently directed, that of establishing a pneumatic institution, where the medical efficacy of the permanently elastic fluids, the fruits of the modern improvements in chemistry, could be fairly put to the test of experiment, by being administered on an extensive scale. The metropolis first suggested itself as an eligible spot for the formation of the projected establishment; but several obstacles having occurred in the execution of this plan, the neighbourhood of Bristol was at length fixed upon as the most proper place for the purpose. In making the various arrangements required in the infancy of such an institution, and which presented peculiar difficulties, he derived material assistance from the cordial co-operation of Mr Edgeworth, the author of *Practical Education*, with whose family he soon became more closely connected, by marrying one of that gentleman's daughters; an event which took place in April 1794. The pneumatic institution continued to occupy his attention for many years, in the course of which, a great number of publications issued from his pen, illustrating the principles on which he expected it to be useful, and detailing the experiments and the results to which it gave rise. The principal of these are the following: "*A Letter to Dr Darwin, on a new mode of treating Pulmonary Consumption*," in 1793; as a supplement to which appeared, in 1794, *Letters from Dr Withering, Dr Ewart, Dr Thornton*, &c. together with an analysis of a paper by Lavoisier, on the state of the air in crowded assemblies, and of another by Vauquelin, on the liver of the skate.—*Considerations on the Medical Use*,

Beddoes.

and on the Production of Factitious Airs, in five parts, which came out successively at different periods, from the year 1794 to 1796.—In 1795, he published an *Outline of a Plan for determining the Medicinal Powers of Factitious Airs.*—In 1797, *Suggestions towards setting on foot the projected Establishment for Pneumatic Medicine:* and *Reports relating to Nitrous Acid*, in confirmation of the efficacy of that remedy in syphilitic affections.—In 1799, *Contributions to Medical and Physical Knowledge, collected principally from the West of England.*—*Notice of some Observations made at the Pneumatic Institution.*—*A second*, and afterwards a *third Collection of Reports relating to Nitrous Acid.* Considerable difficulty was at first experienced in the construction and management of the apparatus required for carrying on the objects of this institution; these were, however, in no long time entirely surmounted by the friendly assistance of Mr Watt, whose exertions at this critical period were eminently serviceable, and are acknowledged in a dedication prefixed to the first part of the *Considerations.* Mr William Clayfield and Mr Read also contributed their assistance in the invention of different parts of the pneumatic apparatus. At the opening of the institution in 1798, the sums subscribed were found to be very inadequate to the purposes for which it was designed; but every deficiency in this respect was amply supplied by the liberality of Mr Thomas Wedgewood, who offered Dr Beddoes L.1000 to enable him to carry the plan into immediate execution. All that was now wanted was to procure a superintendent; and he had the good fortune to engage in that capacity a young man, who had already given proofs of extraordinary talents, and to whose penetrating genius chemistry has since been so deeply indebted. There needs no other indication to suggest the name of Davy,—a name that will descend to distant ages, as associated with so many important discoveries in philosophical science. The history of the pneumatic institution, indeed, derives considerable splendour from many of these discoveries, which were perfected in its laboratory, and which were first announced to the world through the medium of the publications above mentioned; and in the work entitled *Researches, Chemical and Philosophical; chiefly concerning Nitrous Oxide, or Dephlogisticated Nitrous Air, and its Respiration.* By Humphrey Davy, Superintendent of the Medical Pneumatic Institution. London, 1800. The discovery of the chemical properties of this gas, and of its astonishing effects on the system when respired, were among the first, and must ever be esteemed the most brilliant, of the results of this institution; it raised the most sanguine anticipations in the mind of Dr Beddoes, and called forth all his eloquence in the description of what it already had and might be expected to accomplish. These, like the other splendid visions, in which his ardent imagination was but too prone to indulge, have never been realized; and have even created, by their signal failure, an unfortunate prejudice against future attempts to improve the art of medicine by novel methods of treatment founded on chemical or philosophical principles. The original objects of the institution being found unattainable, were successively abandoned, and it assumed, by insensible gradations, the form of the more common establishments for the relief of the sick; and the prevention rather than the cure of diseases became the principal aim of its conductors. In 1807, it was finally relinquished by Dr Beddoes to the care of Mr King and Dr Stock.

Beddoes.

A great variety of medical topics in the meantime engaged the active mind of Dr Beddoes, and gave employment to his pen. In the strictly practical branch of the art we may enumerate, in addition to the works above mentioned,—in 1793, *A Letter to Dr Darwin on a new mode of treating Pulmonary Consumption.*—In 1795, an edition of *Brown's Elements of Medicine*, with a preface and notes.—Translation from the Spanish of *Gimbernat's new method of operating in Femoral Hernia.*—In 1799, *Popular Essay on Consumption.*—In 1801, *Essay on the medical and domestic Management of the Consumptive, on Digitalis, and on Scrofula.*—In 1807, *Researches, Anatomical and Practical, concerning Fever as connected with Inflammation.* In this latter work he successfully combats the theory of Dr Clutterbuck and of Ploucquet, in which fever is supposed to consist essentially in topical inflammation or its membranes.

The object which Dr Beddoes had ever most at heart was, to excite a lively and general attention to the means of preserving health, and of repelling the first inroads of disease, by the diffusion of medical knowledge throughout all ranks of the community, as far as they were capable of acquiring it. His attention was uniformly directed to this favourite object, and he suffered no opportunity to escape of enforcing those maxims which tend to prevent the necessity of the interference of his art. His works on popular subjects, on the improvements of medical education, and the exercise of the profession; and the popular lectures which he promoted, and in which he himself took an active part, all tended to this object. To this head may be referred the following publications: In 1794, *A Guide for Self-preservation and Parental Affection. A Proposal for the Improvement of Medicine.*—In 1797, *A Lecture Introductory to a Popular Course of Anatomy.*—In 1798, *A Suggestion towards an Essential Improvement in the Bristol Infirmary.* But more especially his *Hygeia, or Essays, Moral and Medical, on the causes affecting the Personal State of the Middling and Affluent Classes*, in 3 vols. 1801-2; in which he embraces a great variety of topics, and describes, with a glowing pencil, and occasionally with extraordinary eloquence, the sufferings of patients under different diseases. In 1806, there appeared *The Manual of Health, or the Invalid conducted safely through the Seasons.*—In 1808, *A Letter to Sir Joseph Banks on the prevailing Discontents, Abuses, and Imperfections in Medicine;* and, in the same year, *Good Advice for the Husbandman in Harvest, and for all those who labour hard in hot Births; as also for others who will take it in Warm Weather;* which was the last production he ever wrote, his death happening soon after, of dropsy and enlargement of the pericardium, in December 1808.

Dr Beddoes has been very justly characterized as a

Beddoes || Bedfordshire.

pioneer in the road to discovery. He was full of ardour and enterprise in the pursuit of knowledge, and was easily captivated by every new project that seemed to lead towards any practical improvement. He was more active, however, in exciting the labours of others, than in labouring himself in the field of experiment. He had the imagination of a poet, and could paint in the most vivid colours the sufferings entailed by disease, and enforce with the most powerful eloquence whatever he wished to impress on the minds of his readers. He has been accused of versatility of opinion; but, if he was, perhaps, hasty in publishing the first conceptions which he formed, he has atoned for this fault by the remarkable candour with which he retracted them the moment his confidence in them was shaken. He took a decided line in politics, as appears from the following political publications of his, which appeared in 1795, 1796, and 1797: viz. *A Word in Defence of the Bill of Rights against Gagging-Bills.—Where would be the Harm of a Speedy Peace?—An Essay on the Public Merits of Mr Pitt.—A Letter to Mr Pitt on the Scarcity.—Alternatives Compared, or What shall the Rich do to be Safe?*

See Dr Stock's *Memoirs of the Life of Dr Beddoes*, London, 1811. (W.)

BEDFORDSHIRE. The article, in the original work, on this county, is almost exclusively confined to its ancient history, and its antiquities, and in the short notices which it gives on other points, it is by no means accurate. In this article, therefore, we shall attend to what is omitted or incorrect in the former.

Boundaries and Extent.

This county possesses no natural limits, except the Ouse for a short space on the east and west sides, and a rivulet on the south-west border. It is situate between the parallels of 51.47 and 52.17 north latitude, and between 0.17 and 0.46 west longitude from Greenwich. According to the report to the Board of Agriculture, it contains 307,200 acres; according to the returns to Parliament of the poor-rates, drawn up under the inspection of Mr Rose, 275,200; and according to Dr Beeke, in his *Observations on the Income Tax*, 293,059. Nearly the whole of this county is situate on the eastern side of the grand ridge of the island, and consequently nearly all its waters drain off in that direction.

Face of the Country.

The face of the country is, in general, varied with small hills and valleys, and affords few extensive level tracts. The highest range of hills are the Chiltern, which cross a part, and skirt the remainder of the southern extremity of this county. This ridge frequently projects abruptly into the valleys in a striking manner. Under it is a large tract of hard, steril land, which gives this part a dreary and uncomfortable appearance. The next most considerable range, in point of height, is of clay, crossing the county near its northern end. The next range is of sand, and enters the county on its western side, near Apsley-Guise, and passes on in a north-eastern direction. The other ranges are for the most part of alluvial clay.

Strata.

Four-fifths of the surface of this county are covered with alluvial soils, which consist principally of yellow and dark coloured clays. Fuller, speaking in general terms of its soil, gives a pretty just description of it, by saying, that it is a deep clay with a belt or girdle of sand about, or rather athwart the body of it, from Woburn to Potton. This soil prevails in the north-west parts. From the south-eastern corner to the middle of the county, light loam, sand, gravel, and chalk predominate. Th ewestern part is, for the most part, flat and sandy. In the south-west, about Woburn, are large tracts of deep barren soil. Upon the gravel, in the bottoms of the vales in the sand district, there is a considerable quantity of peat, which contains a large quantity of sulphuric acid.

The uppermost stratum in Bedfordshire is a thick body of chalk, with numerous layers of flints. This advances no farther northward or north-west than Luton and Dunstable. Hard chalk, without flints, succeeds. Near the bottom of this is a very durable freestone. The upper and lower chalk strata are together about 400 feet thick. Chalk-marl succeeds the chalk. To the northward of Hockliff there are thick masses of alluvial clay. The ferruginous sand stratum of Woburn crosses the county, as has been already mentioned, from Woburn to Potton. It is about 170 or 180 feet thick. Near the bottom of it are beds of fuller's earth. This substance is found from five to seven or eight feet thick, between beds of sand or sandstone, over several hundred acres on the north-west of Woburn, both in Bedfordshire and Buckinghamshire. Formerly, the most extensive workings were in Apsley-Guise parish, in the former county; but, at present, the only pit that is used is in Buckinghamshire. The site of Bedford is formed of a stratum of clunch clay; it is the thickest of the Bedfordshire strata, and extends for several miles to the south side of the county town. In some parts of this stratum, there are beds of argillaceous schist, so impregnated with a bituminous substance as to burn like bad coal. In the immediate site of the town of Bedford are several strata of grey compact limestone, which are probably the lowest strata in the county. The strata of Bedfordshire have a pretty regular dip towards the south-east, at the rates of 1 in 50 to 1 in 80.

Rare Plants.

Amongst the most rare of the indigenous plants of this county may be enumerated *Lythrum hyssopifolium*, grass-poly, or small hedge-hyssop, which grows plentifully in the fields between Oakley and Clapham; *Campanula latifolia*, giant throat-wort, and *Eriophoron polystachion*, cotton grass, near Dunstable; *Geranium phæum*, spotted cranes-bill, near Eversholt; *Hyoseris minema*, small swines' succory, near Aspley and Ampthill; and *Ornithogalum pyrenaicum*, spiked star of Bethelem, near Eaton-Locon. Dr Abbot, who has published a very ample *Flora* of the indigenous plants of this county, found the *Euphorbia cyparissias*, considered as a doubtful native plant, growing wild in Barton-lect woods.

Climate.

According to meteorological observations made at Leighton-Buzzard, the monthly mean for four years, ending the 1st of January 1804, of the barometer, was 29.520; of the thermometer, with a northern aspect, observed at eight o'clock in the morning, without the house, 47.2, within the house, 49.6; of rain, 1.93 inches; and of evaporation, 1.05. The most prevalent wind, during that period, was south-west by west.

Bedfordshire.

Rivers.

The principal rivers in this county are the Ouse, the Ivel, and the Ouzel. The circuitous course of the first has been much exaggerated. As it is described on Jeffries's map, which was made by a trigonometrical survey, its course does not appear to be more than 45 miles. It enters this county from Buckinghamshire, in the parish of Turvey, and, taking a winding course through fertile meadows, passes the town of Bedford, from which it becomes navigable, and makes its exit into Huntingdonshire. Its stream is remarkably slow, except in time of floods, when it is liable to great inundations. Its average depth is about ten feet. The fish of the Ouse are pike, perch, bream, chub, bleak, cray-fish, eels, dace, roach, and gudgeon. The eels are of a very large size, in great abundance, and very fine. The Ivel enters Bedfordshire near Stodfield. At Biggleswade it becomes navigable, and at Tompsfurd falls into the Ouse. It is particularly famous for gudgeon. The Ouzel separates this county from Buckinghamshire, in its course to Leighton-Buzzard. The Lea rises in Bedfordshire, and runs through the whole extent of Luton parish. The Grand Junction Canal touches the borders of this county for about three miles, near Leighton-Buzzard.

Landed Property.

There are several very large estates in Bedfordshire, the principal of which belong to the Duke of Bedford, the Marquis of Bute, the Earl of Upper Ossory, Lord St John, Earl Spencer, and Mr Whitbread. The principal agricultural products are corn and butter. Much of the former is sent down the Ouse to Lynn, and the latter goes principally to London by land-carriage. This county has been long noted for its abundant produce of fine wheat and barley. The vale of Bedford is one of the most extensive corn districts. The rich dairy ground principally extends in a line, from the middle of the county to the south-east corner. In some parts of Bedfordshire, especially in the parish of Sandy, garden vegetables are raised in considerable quantities for the supply of the neighbouring towns. The agriculture of this county, it is well known, was extremely indebted to the judicious and liberal patronage and example of the late Duke of Bedford. His favourite pursuits were experimental agriculture and the breeding of cattle. For these purposes, he kept several farms in his own hand. The principal farm-yard is in Woburn park. The buildings of every kind are upon the most extensive scale, and abound in every convenience. One of the most remarkable is the room constructed for showing the sheep at the annual shearing. On the farm at Woburn is a mill for malting, thrashing, winnowing, &c. The cultivation of woad, mentioned by former writers as carried on to a considerable extent in Bedfordshire, has long been laid aside. On what are called the "woodland soils," and on the colder parts of the alluvial clay, particularly the steep sides of the hills, in the northern and middle parts of the county, there are between 6000 and 7000 acres of very old wood. There are also about 500 acres on the sand, where also large plantations of fir have been made. A considerable part of the timber that is felled is sent to the sea coast by the Ouse.

Produce.

Woburn.

Woods.

Manufactures.

The principal manufactures are the plaiting of straw, and making it into bonnets, &c. and thread-lace. The straw manufacture prevails, and latterly has much increased, in the neighbourhood of Dunstable and Toddington, and on the borders of Hertfordshire. The employment is deemed more healthy than that of lace-making, as the straw may be plaited by persons standing or walking. The earnings, even of those who make the coarse plait, are higher than those of the lace-makers; and the profit of making the fine plait is very considerable. Thread-lace, formerly known by the name of bone-lace, was for a long time the staple manufacture of this county; but latterly it has given way to the manufacture of straw; and has farther declined in consequence of the general introduction of cotton-lace. It is now made only in a very few villages in the neighbourhood of Buckinghamshire, and in the town of Bedford. It is not so fine in its texture as the lace made in some parts of Buckinghamshire. The average day's-work of an adult, when the manufacture flourished, was rather more than a shilling a-day; the children earning from threepence to sixpence. The posture in which the manufacturers sit, the sedentary nature of the employment, and the habit of working together in crowded rooms, ill ventilated, give the manufacturers a weak and sickly appearance. In the neighbourhood of Dunstable, there is a whiting manufactory, which employs a few people.

Population

In the year 1377, the number of persons in this county who were charged to a poll-tax, from which the clergy, children, and paupers were exempted, amounted to 20,239. This tax was levied not long after a fatal pestilence. In the year 1700, the total population was estimated at 48,500; in 1750, 53,900. By the returns to Parliament, in 1801, the number of inhabited houses was 11,888; of uninhabited 185; the number of families was 13,980; the number of persons chiefly employed in agriculture was 18,766; the persons chiefly employed in manufactures, trade, and handicraft, 13,816; and persons to whom no occupation was assigned, and children, was 28,789: the total number of resident inhabitants was 63,393; of whom 30,523 were males, and 32,870 females. The population, in 1811, had increased to 70,213; of whom 33,171 were males, and 37,042 females; the number of inhabited houses was 13,286; of families 14,927; of houses building 139; of houses uninhabited 219:—the number of families employed in agriculture was 9431; and the annual value of the land at rack-rent was nearly L.280,000. The number of families chiefly employed in trade, manufactures, &c. was 4155; and the amount of annual profits was rather more than L.94,000. The number of people to a square mile was 171; the annual proportions of baptisms was 1 to 32 persons; of burials, 1 to 56; and of marriages, 1 to 126.

Poor-rates.

In the year 1776, the amount of the poor-rates raised in this county was L.18,193; in the year 1784, L.22,638; and in the year 1803, L.47,484. This was at the rate of 3s. 9¾d. in the pound, on a rental of L.248,600, or 14s. 9¾d. a head, on the whole population. The total expenditure for the poor, in 1803, was L.38,070; nearly L.10,000 being ex-

pended in law-suits, county-rates, &c.; L.37,944 was distributed to 7276 persons, or 1 in every 8-$\frac{7}{9}$th of the whole population, the average allowance being 2s. a week. Of these paupers, 674 were wholly maintained in work-houses, at the average expence of L.12, 10s. 5½d. each annually, or 4s. 9¾d. per week. There were at that time 2370 persons associated in 75 Friendly Societies: eight parishes in the county had schools of industry, in which 196 children were taught to work. Only an incomplete return has as yet been made to Parliament of the poor-rates, or other rate or rates raised in Bedfordshire, in the year ending 25th March 1815; six parishes out of the 140 having made no return; but it appears, from the return actually made, that 134 parishes paid, at that time, L.69,464, 6s. 3¾d.

Gothic Architecture.

Remains of the earliest style of Gothic architecture are to be seen in this county, in the nave of Elstow church, in the west part of Folmeisham church, and in the west end of Dunstable church. Of the succeeding style of Gothic architecture, which prevailed during the fourteenth century, few examples are to be met with in Bedfordshire. Wimmington church, however, though small, is an elegant specimen of it, and appears never to have been altered. Several of the Bedfordshire churches are in the latter style of Gothic architecture, which prevailed during the fifteenth, and the beginning of the sixteenth centuries. The churches of Northill, Wilmington, Mayton, Eaton-Socon, Odill, Biggleswove, and St Paul's at Bedford, are in this style.

Historical Notices.

In the original work, there are notices of the history of this county till the time of Alfred. Nothing important occurred in it for several centuries afterwards. During the civil wars between the houses of York and Lancaster, it presents no remarkable events, probably in consequence of the destruction of its castles by King John, in his march northward. But Bedfordshire was one of the first counties that associated against Charles I.; and Lord Clarendon observes, that this was one of the counties in which the King had not any visible party, nor one fixed quarter.

Town of Bedford.

To the notice of the town of Bedford, in the original work, some particulars may be added. It is 50 miles north-west by north from London; the latitude of St Paul's church, according to the government trigonometrical survey, is 52, 8, 8, 8, north; and its longitude 0, 27, 43, 3, west of Greenwich Observatory, or 1′, 50″, 9, in time. The right of election is vested in the burgesses, freemen, and inhabiting householders not receiving alms; their number is about 1400. Besides its parish-churches, its public buildings, are a county-infirmary, a county-jail, and bridewell, a town-jail, and a county-hall. It is situate rather to the north of the centre of the county, and in the midst of a very rich tract of land, called the Vale of Bedford. The Ouse is navigable from the Eastern Sea to this town. By its situation, on this river, the inhabitants carry on a considerable trade in forwarding the corn of the adjacent fertile country to Lynn; and in importing from thence coals, timber, wine, and groceries. The inundations of the Ouse have been more frequent and destructive latterly than they used to be, in consequence, it is supposed, of the many newly inclosed parishes, which drain into the river. There is sometimes a stagnation of water in the meadows of the Ouse, near Bedford, to the depth of 12 or 14 feet.

Thread-lace is the principal manufacture of the place. According to the Parliamentary returns of 1801, of 3948 inhabitants, which it then contained, there were 2236 females. This great disproportion between the sexes has been justly ascribed to the will of Sir William Harper, who, in the year 1561, bequeathed 13¼ acres of land in the parish of St Andrew, Holborn, to the corporation of Bedford, for the support of a grammar-school, and the apportioning young women of the town upon marriage. The rent of this estate being now between L. 4000 and L. 5000, it may well be supposed that young women from the vicinity of Bedford are drawn into the town in the hope of getting apportioned and married. In 1811, the population of the town consisted of 2057 males, and 2548 females; the inhabited houses were 940, and the families inhabiting them 1099.

The principal market at Bedford, held on Saturday, on the north side of the river, is a considerable mart for corn. The Monday market, on the south side of the river, is chiefly for pigs. There are six annual fairs, besides a fair held in the vicinity at St Leonard's Farm.

It is generally supposed that Bedford is the Bedanford of the *Saxon Chronicle*, where the battle was fought between Cuthwulf and the Britons in 572; it is said to have been the burial place of Offa, king of the Mercians. According to *Doomsday-book*, it was taxed as half a hundred, both for soldiers and shipping. Before the Conquest, there was a collegiate church here, dedicated to St Paul. The celebrated John Bunyan was porter of an independent meeting-house in Mill Lane, from 1671 till his death in 1688. His memory is much revered by the congregation, and the chair in which he used to sit is preserved as a relic in the vestry. The Moravians have had an establishment at Bedford ever since the year 1745.

BEE.

Progress of Knowledge regarding this Insect.

THE Bee, from its singular instincts, its active industry, and the useful products resulting from its labours, has, from the remotest times, attracted the attention, not only of naturalists, but of mankind in general. No nation upon earth has had so many historians as this remarkable tribe of insects. The patience and sagacity of the naturalist have had an ample field for exercise in the study of their struc-

ture, physiology, and domestic economy. Their preservation and increase have been objects of assiduous care to the agriculturist; and their reputed perfection of policy and government, have long been the theme of admiration, and have afforded copious materials for argument and allusion to the poet and the moralist in every age. It is a subject that has been celebrated and adorned by the muse of Virgil, as well as illustrated by the philosophic genius of Aristotle. Cicero and Pliny report that Aristomachus devoted himself during sixty years to the study of these insects; and Philiscus is said to have retired into a desert wood, that he might pursue his observations on them without interruption. A prodigious number of authors have written express treatises on bees; periodical works have been published relating exclusively to their management and economy; and learned societies have been established for the sole purpose of conducting researches on this subject. The most celebrated association of this kind is the *Société des Abeilles*, founded about fifty years ago in Little Bautzen, a village in Upper Lusatia, under the auspices of the Elector of Saxony. Its labours, as we shall presently find, have enriched the science with a number of valuable discoveries.

In so complicated a branch of natural history, the application of the difficult art of observing correctly, and of the cautious processes of induction, cannot be effected without laborious and long continued efforts. But, on the subject of bees, the inquirer after truth had, besides, many obstacles to encounter, from the very general diffusion of errors, which had been transmitted without due examination from one author to another. The history of the opinions of successive writers, will sufficiently prove how gradual and how slow has been the advancement of real knowledge in what concerns these insects, and will teach us to estimate the value of that which we at length possess, as being the result of the labour of ages, and as being extorted from nature by indefatigable and persevering exertions. So great an accumulation of curious and interesting facts, indeed, has accrued to us from the researches of Swammerdam, Maraldi, Reaumur, Schirach, and Huber, as to constitute almost a new science. Many of these have been discovered subsequent to the time of the compilation of the article Bee in the *Encyclopædia*. It will therefore be proper, in this place, to give a connected and systematic account of the natural history of this remarkable insect. For the details of the external characters and distinctions of species, we shall refer to what has been already stated in the above article, and in that of Entomology. The principal features of their internal conformation will be described when treating of the particular functions to which they are more immediately subservient; and our descriptions will apply, more especially, to the common and best known species, the *Apis mellifica*, which is the one particularly prized on account of the rich products it affords.

[Pl]an of this [ar]ticle.

The economy of bees comprehends so wide a field of inquiry, the different parts of which are so connected and dependant upon one another, that it is impossible to treat of them distinctly, without supposing the reader to possess some general acquaintance with the history of these insects. We shall, therefore, premise a brief account of the different sorts of bees inhabiting the hive, and of the respective offices of each. We shall then proceed to consider their comparative physiology; under which head we shall state the leading particulars relating to their nutrition, secretion, respiration, progressive motion, external senses and instincts. We shall next follow them in their different labours, from the period when the swarm has settled in a new habitation; we shall detail the complex structure of their hives,—their curious processes of architecture,—the pains they bestow on rearing their progeny and in sending forth new swarms; and this will lead us to the subject of the fecundation of the queens, and the massacre of the drones. After having thus given an account of their usual condition, we shall, in the last place, describe the result of several experiments and observations, which have been made when they were placed in unusual circumstances; experiments which have exhibited many interesting features of their character, and have thrown considerable light on the whole of their history, as well as suggested various practical and economic applications in the management of these insects.

Functions of the Males, Females, and Neuters.

The leading feature in their history, and one which distinguishes them from almost all insects, is their singular distribution into three different kinds, constituting, to all appearance, so many different modifications of sex. The drone, which is characterized by a thicker body, a round head, a more flattened shape, and more obtusely terminated abdomen, within which are contained the male organs of generation, has been admitted as the male of the species. It is distinguished, also, by the absence of a sting, and by the humming noise that accompanies its flight. The queen-bee, which is larger than any of the others, has the abdomen of greater length, and is provided with a sting, and with two ovaria of considerable size, is unequivocally recognised as the female. The working-bees compose the third class, and are distinguished by the smallness of their size, their lengthened proboscis, the peculiar structure of their legs and thighs, which are adapted to the collection of certain materials collected from vegetables, and by the apparent absence of every trace of generative organs,—we say apparent absence, because, as will be hereafter stated, rudiments of ovaria have been very lately discovered to exist, which, however, are not perceptible without a very minute and careful dissection. Till within a few years, the working-bees were regarded as animals deprived of sex, and were accordingly termed *neuters* or *mules*. It is these which perform all the laborious offices for the community,—which construct the interior of their habitation,—which explore the country in search of nourishment and other materials,—which collect and bring them to the hive, and apply them to different purposes; it is they who assiduously attend upon the queen, and supply all her wants,—who defend the hive from the attacks of depredators,—and who carry on hostilities against the various enemies of the tribe. The life of the females is chiefly engrossed

Bee.

with the duties of laying eggs, and conducting the colonies, which, at certain periods, emigrate from the parent state. The drones, producing neither wax nor honey, and depending on the rest for their subsistence, are idle spectators of these labours. They appear to be formed only for the momentary, but important duty of impregnation; since they perish when this purpose is accomplished. There is commonly only one perfect queen existing at a time within each hive; and she appears to be treated by all the other bees with every mark of affection and of deference. The number of labourers is very different in different hives; sometimes there are only a few thousands, at other times, from twenty to forty, or even fifty thousand. The drones, even in the spring, seldom compose more than one-thirtieth, or one-fortieth of the whole; and, at other seasons, there are none to be found in the hive. In order to form some estimate of the number of bees which can occupy a certain space, Mr Hunter counted what number of drowned bees could be contained in an alehouse pint, and found it to be 2160; so that if a swarm were to fill two quarts, their numbers would be nearly 9000. Reaumur, with the same view of ascertaining their numbers, employed the more accurate method of weighing them; he found that a collection of them, weighing one ounce, consisted of 336 bees; and, therefore, that 16 ounces, or one pound, would consist of 5376 bees.

Real Sex of the Working-Bees.

Notwithstanding these differences in conformation, instincts, and offices between the queen-bee and the workers, it is now established, upon the most incontrovertible evidence, that they both originally proceed from the same kind of larva, and that the queen-bee lays only two kinds of eggs, the one destined to produce the drone, the others capable of being converted, according to circumstances, either into a worker or a queen. It has been proved that the former, although exhibiting no appearance of sexual organs on a superficial examination, are in reality females, and have the rudiments of these organs, which, from their not being developed, are incapable of exercising their proper functions. The principal facts from which these conclusions were derived have already been briefly stated in the article Bee in the *Encyclopædia*, but the evidence was at that time scarcely sufficient to carry complete conviction to the mind. It may be remarked, that the idea of the working-bees being radically females had been given out long ago by Dr Warder, in his *Monarchy of Bees*, in which he terms them "True Amazones;" but no attention had been paid to his opinion. The real merit of this great discovery, which affords the key to a multitude of hitherto inexplicable facts, unquestionably belongs to Mr Schirach, vicar of Little Bautzen, the Secretary of the Lusatian Society, to which we formerly adverted. When first announced to the world, it was received with suspicion by the greater number of naturalists, and with complete incredulity by others. It was, indeed, at variance with the whole tenor of the observations of Swammerdam, Maraldi, and Reaumur. Wilhelmi, the brother-in-law of Schirach, though an eye witness to the experiments from which he had deduced this theory, for a long time refused to admit the doctrine; but became at length one of its most strenuous supporters. It is noticed in a vein of sarcastic ridicule by Mr John Hunter, in his otherwise excellent paper on bees in the *Philosophical Transactions*. Needham wrote a memoir for the Imperial Academy of Brussels, in 1777, for the express purpose of refuting it; and he then inveighs in strong language against those naturalists who had deigned to give it the least countenance. Mr Key, in the *Bath Society Papers*, declares that he made experiments on this subject for eight years, without obtaining a single result in conformity to Schirach's views. Bonnet, after exercising a laudable scepticism, and making a diligent inquiry, in which he displays a genuine spirit of philosophy, yielded a reluctant assent. But the truth of the doctrine has since been placed beyond the reach of controversy by multiplied series of observations and experiments in different parts of Europe; and more especially by the recent investigations of Mr Huber of Geneva. We shall not at present enter into the detail of proofs, because their force will be better appreciated when other particulars belonging to the history of the bee have been explained.

Nutrition.

In considering the physiology of the bee, the first function that claims our notice is that of Nutrition. The food of bees is principally of two kinds; namely, the fluid secretions of vegetables contained in the nectarea of the flowers, and the dust of the antheræ, which has been termed by botanists the pollen, but which, when collected by the bees, has received a variety of appellations, such as farina, bee-bread, raw wax (*cire-brute*), &c. Occasionally, however, we find bees feeding upon other saccharine substances besides honey, such as honey-dew, treacle, syrup, &c.

Nature of the Food of Bees.

Organs of Collecting Food.

The organs by which they collect food are extremely complex, for they comprise instruments adapted to the reception of liquid aliment, as well as those fitted for the division of solid materials. Reaumur has given the most elaborate description of these organs, in which he has corrected some errors that Swammerdam had fallen into. For the purpose of taking up fluids they are provided, in common with all hymenopterous insects, with a long and flexible proboscis or trunk, which may be considered as a lengthened tongue, though, strictly speaking, it is formed by a prolongation of the under lip. It is not tubular, as Swammerdam had supposed, but solid throughout, and the minute depression at its extremity is not the aperture of any canal through which liquids can be absorbed. Cuvier, in his *Leçons d'Anatomie Comparée*, has not marked this distinguishing feature in the proboscis of the bee, but speaks of it in common with the tubular trunks of the other hymenoptera, and describes its aperture as being situated in the lower part. But Reaumur has very satisfactorily shown that the trunk of the bee performs strictly the office of a tongue, and not that of a tube for suction, for when it takes up honey or other fluid aliment, the under or the upper surfaces are more immediately applied to it, and rolled from side to side, and the bee thus licks up what adheres to it, while the extremity of the trunk is frequently not applied at all to the substance ta-

Proboscis.

 ken up. The trunk is supported on a pedicle which admits of being bent back, or propelled forwards, and thus can retract or stretch out the trunk to a considerable extent. Protection is given to it by a double sheath; the external consisting of two scales furnished by the expansion of one of the portions of the labial palpi, and the internal, formed by the prolongation of the two external portions of the jaw. The whole member thus consists of five principal parts, on which account Fabricius termed it *lingua quinquefida*.

Mandibles. For the purpose of mechanically dividing solid materials, the mouth is furnished with two strong mandibles and four palpi; they are but little employed in eating, but are of great use in enabling the insect to seize and break down hard substances for other purposes. In the working-bee all these parts are of larger dimensions than in the other kinds. The teeth are two in number, and have the form of concave scales with sharp edges; they are fixed to the ends of the jaws, and play horizontally as in other insects. Reaumur describes and delineates a large aperture above the root of the proboscis, which is so surrounded with fleshy parts as not to be readily seen, unless the proboscis be extended and bent downwards. This he considers as the mouth or orifice of the gullet; on the upper side of which, and of course opposite to the root of the proboscis, a small fleshy and pointed organ is seen, which he regards as the tongue, assisting in the deglutition of the food. Through this orifice, it is presumed, all the aliment, whether liquid or solid, passes; the former being conveyed to it by the trunk, which, by its contractile power, presses forward the fluids it has collected between itself and the inner sheath, and the latter being received directly after its comminution by the teeth, behind which it is situated. Latreille, however, whose authority is great on a point of this nature, thinks that Reaumur has deceived himself with regard to such an aperture, and disbelieves its existence. He conceives that the food simply passes on by the sides of the tongue, finding its way from thence into the œsophagus, and so on to the stomach.

Stomachs. The bee has two stomachs: The first is a large transparent membranous bag, pointed in front, and swelling out into two pouches behind. It performs an office, in some respects, analogous to that of the crop in birds; for it receives, and retains for a time, the fluid of the nectarea, which does not appear to differ, in any respect, from honey. Mr Hunter observes, that, whatever time the contents of this reservoir may be retained, he never found them altered, so as to give the idea of digestion having taken place. The coats of this reservoir are muscular, by which means it is capable of throwing up the honey into the mouth, so that it is regurgitated into the honey cells, or imparted to other bees. None of it ever passes out from the extremity of the trunk, as Swammerdam had believed. For the purpose of digestion, a second stomach is provided, which takes its origin from the middle of the two posterior lobes of the former, and is of a lengthened cylindrical shape. Its communication with the intestine is not direct, but takes place by a projecting or inverted pylorus, thickest at its most projecting part, with a very small opening in the centre, of a peculiar construction. This inward projecting part is easily seen through the coats of the reservoir, especially if full of honey. A similar kind of structure takes place at the communication of the first with the second stomachs, and, having the properties of a valve, must effectually prevent all regurgitation from the latter into the former.

Collection of Pollen. The pollen of flowers, which is the other principal article of food, was shown by Swammerdam to consist of an infinite number of small particles, generally of a globular shape, each of which is found to be a small capsule, enclosing the still finer dust or fecundating principle, destined to be shed on the pistils for the purpose of germination. Geoffroy has given a memoir, published in the *Collection Académique des Sciences*, containing a minute description of the shapes of these capsules, taken from different flowers. The working-bees, by means of the pencil of hair which grows on the tarsi, first collect a certain quantity of pollen, which they knead together into a ball, and place it in the concave space which is situated at the middle joint of the hinder feet, and has been termed the basket. The surrounding rows of hairs keep the ball from falling off. In order to gather larger quantities at once, the bees are sometimes observed to roll their bodies on the flower, and then brushing off the pollen which adheres to them with their feet, form it into two masses, which they dispose of as before mentioned; and it is said, that, in moist weather, when the particles of pollen cannot be readily made to cohere together, they return to their hive, dusted all over with pollen, which they then brush off with their feet. They are often obliged to tear open the capsules which contain the pollen, in order to procure a supply of this substance, when it has not yet been shed by the flowers.

Pollen is yielded by flowers during the spring in such abundance, that the bees of a single hive will often bring back one pound, or even more, in a day. Some agriculturists have accordingly imagined, that the vegetation of some plants might be endangered from this great consumption of the fecundating principle by insects in general; for other insects, besides bees, seek it with great avidity. But this fear has been proved to be totally without foundation, and the practice of destroying bees in order to prevent this imaginary danger, is therefore as useless as it is barbarous. It would appear, indeed, that so far from obstructing the fecundation of plants, the labours of the bee have often tended materially to promote it, by the agitation which they gave to the flower, and by transporting the pollen from one flower to another. In this manner may we account for the number of hybrid flowers that are met with near the haunts of bees.

It has been shown very clearly by Huber, in a paper in the *Journal de Physique*, that pollen is peculiarly the food of the young bees, and is collected by the working-bees with this intention. Reaumur, however, asserts that he has seen adult bees devour pollen. Swammerdam, who conceived the trunk to be tubular, rejected the idea that pollen could ever be the food of bees, as the globules of which it con-

sists are incapable of entering an orifice so minute as that which appears at the extremity of the trunk, and which, as he was unacquainted with the real mouth, he thought was the only passage to the stomach. Latreille, who does not admit the existence of the large mouth described by Reaumur, states that the mandibles lay hold of the pollen, and carry it to the base of the trunk, from whence it finds its way into the œsophagus, by the sides of that organ.

On the nature of Honey-Dew, and the consumption of it by bees, a sufficient account has already been given in the *Encyclopædia*, under that article.

An abundant supply of water is essential to the healthy condition of bees. They consume a large quantity, and often stop to drink at the edge of stagnant pools, and seem even to prefer putrid and urinous waters to purer streams, as if their saline and pungent qualities were grateful to them.

Production of Wax. It has been long the opinion that wax was but a slight modification of pollen, which required for this conversion merely the application of a certain pressure, and a kind of kneading by the feet of the bees. Many naturalists, such as Bernard de Jussieu, had persuaded themselves that the dust of the stamina of flowers contained wax ready formed, as one of its ingredients; and quoted the following experiment in proof of this opinion: If the minute grains of pollen be put into water, they gradually swell, till they at length burst, at which moment a small jet of an oily liquor will be perceived, which floats on the water without mixing with it. But Reamur had attempted in vain to extract any thing like wax from dust of the antheræ; and, indeed, an attention to the chemical properties of these two substances would have sufficiently pointed out their essential differences. From the upper surface of the leaves of many kinds of trees, a substance has, indeed, been obtained, which possesses all the qualities of bees' wax; but nothing like it can be extracted from pollen. Reaumur was persuaded that the pollen was elaborated in the second stomach of the bee; and thrown up into the mouth in the form of a white foam, which, by exposure to the air, hardened, and became wax; and that the bee took advantage of its soft state to apply it in the building of the combs. So circumstantial an account, given to us by a scrupulous observer of facts, appeared to be perfectly satisfactory, and was acquiesced in by naturalists in general. But it has since been completely proved by the researches of Duchet, of Hunter, and of Huber, but principally by the latter, that wax is a secretion from the abdomen of the bee; and that it depends not at all on the pollen which the insect may consume, but on the quantity of honey or other saccharine substance which it receives into the stomach. The first step in this discovery was made by one of the members of the *Lusatian Society*, whose name has not been preserved. It was mentioned in a letter of Mr Wilhelmi to Bonnet in August 1768, in which he says that wax, instead of being rejected by the mouth, exudes from the rings which inclose the posterior part of the body. Of this we may satisfy ourselves by drawing out the bee from the cell in which it is working with wax, by means of the point of a fine needle; and we may perceive, in proportion as the body is elongated, that the wax will make its appearance under the rings, in the form of small scales. Mr Duchet, in his *Culture des Abeilles*, gives a full statement of the principal circumstances attending the production of wax, which he very justly ascribes to the conversion of honey into this substance in the body of the bee. These facts appear to have been entirely overlooked till the subject was again brought forward by Mr John Hunter, in his paper in the *Philosophical Transactions* for 1792. Wildman, however, had cursorily remarked, that portions of wax, in the form of scales, and which he conceived must have been moulded on the body of the bee, are sometimes found at the bottom of the hive. M. Huber was prosecuting his inquiries on this subject at the same period with Mr Hunter, and discovered, in 1793, the existence of regular receptacles, or pouches, from the coats of which the wax is secreted, and within which it accumulates till its edges raise the scales, and become apparent externally. These plates of wax are withdrawn by the bee itself, or some of its fellow-labourers, and is applied in a manner hereafter to be described.

Huber has shown, by a series of well conducted experiments, that, in a natural state, the quantity of wax secreted is in proportion to the consumption of honey; but that an equal, or even greater quantity, will be formed, if the bee be fed on a solution of sugar in water. Warmth and rest promote this process of secretion; for the bees, after feeding plentifully on saccharine food, hang together in a cluster, without moving, for several hours, at the end of which time, large plates of wax are found under the abdominal rings. This happened when bees were confined and restricted from any other sort of nourishment; while those that were fed on pollen and fruits alone, did not produce any wax. It appears also from his researches, that the formation of wax is the office of a particular set of bees, which may be distinguished from the rest, and particularly from those that nurse the young larvæ, by the greater size and more cylindrical shape of their abdomen. Dissection also shows that their stomachs are more capacious. Having already given the details of the experiments of Huber on this subject, in the article Entomology, in the *Encyclopædia*, there is no occasion to dwell on them farther. In the second volume of Huber's *Nouvelles Observations sur les Abeilles*, he describes minutely the anatomy of the pouches or receptacles for the wax, which are parts peculiar to the working-bees, being totally absent in the males and queens. It is a structure that had escaped the keen eyes of Swammerdam, and has not been noticed by any subsequent anatomist. The cavities are lined with a membrane, which presents a number of folds, forming a hexagonal net-work, not unlike the appearance in the second stomach of ruminant quadrupeds, and evidently destined to perform the office of secretion.

Among the secretions peculiar to the bee, the poison which is poured into the wounds made by the sting deserves to be noticed. But for an account of this, as well as of the organ itself, we shall refer the reader to the article Bee, Sect. 2.

Bee.

Function of Respiration:

As it is well known that no organs for the circulation of blood are provided in insects, this function composing no part of their economy, respiration must be effected by means totally different from those which are adopted in the higher classes of the animal kingdom. As the blood, or fluid corresponding to the blood, cannot be presented to the air in any separate organ, the air must be conducted to the blood, wherever such a fluid is met with. For this purpose, tracheæ or air-tubes, having several external openings, or spiracles, are made to ramify like arteries, and are distributed in an infinite number of branches to every part of the body. The analogy of other insects might perhaps be admitted as sufficient evidence that bees respire atmospheric air, the constant renewal of which is essentially necessary to the continuance of the vital functions. It is, however, not always safe to trust to analogical reasoning in subjects of natural history; and direct evidence is, in all cases, to be preferred when it can be obtained. We must, therefore, consider as valuable, the complete series of experiments on the respiration of bees, that have been lately given to the world by Huber, to whom we already owe so large a portion of the information we possess with regard to these insects. We might, indeed, have anticipated, with the strongest probability, many of the results to which these experiments have led; but there are others which are quite unexpected, and possess as much interest as of novelty.

The condition of a hive of bees, in which many thousand individuals, full of animation and activity, are crowded together in the very small space of one or two cubic feet, having no communication with the external air but by means of a small aperture in the lowest part, which entrance is frequently obstructed by a throng of bees, that are passing in and out during sultry weather, is of all possible conditions the one least favourable to the renewal of heated air. The most crowded theatres or hospitals are not to be compared with it in point of closeness. Direct experiment, indeed, shows that the combustion of a taper could not be carried on in so limited a space, for Mr Huber found that in a glass ball of the same dimensions as the hive, and with a similar aperture, the taper went out in a few minutes. So great was the difficulty of explaining the respiration of bees under these circumstances, that Mr Huber was led to examine into the truth of the opinion, that respiration was equally necessary to bees as to other insects. The results were unequivocal. They perish speedily in the vacuum of the air-pump. They are easily drowned by placing them so that the spiracles on the corslet are under water; but revive easily when they are dried. The action of the spiracles is, in this experiment, rendered manifest by the escape of bubbles of air from each of their orifices. When a number of bees are confined in a bottle accurately closed, they exhibit unequivocal symptoms of distress, and fall into complete asphyxia. These changes occur more rapidly when they are placed in any gas which contains no admixture of oxygen, such as carbonic acid, hydrogenous and azotic gases. When rendered torpid by cold, and respiration thereby suspended, these effects do not take place. All these effects are more considerable in adult bees than in the larvæ; though they are also distinctly exhibited in the latter. Suffocation is retarded if the proportion of oxygen be greater than in atmospheric air, and it may be averted altogether by a continual renewal of oxygen. It was ascertained by the endiometer, that the same changes were produced on the air as in the respiration of other animals; namely, the subtraction of oxygen, and the addition of an equal volume of carbonic acid gas.

Its Necessity.

Yet, on examining the air of the hive itself, it was found scarcely to differ in purity from atmospheric air. It was at one time conjectured that some of the contents of the hive, such as the pollen, the honey, or the wax, might have some power of evolving oxygen, so as to afford the requisite supply of this gas. Experiments, however, proved that they had no such power. Amidst so great an uncertainty, it was thought worth while to ascertain whether bees might not exert some unknown process, by which oxygen was generated in the hive itself. If this were true, they could support life, although all communication with the external air were intercepted. A hive was selected, having glass sides so as to allow of the observer's seeing what was passing in the interior, and the entrance was completely closed. In a quarter of an hour, the bees became sensible of their situation, and showed great uneasiness; all business was suspended; an extraordinary agitation, accompanied by a remarkable noise, prevailed in every quarter. All the bees were seen beating their wings with the same rapidity as in flying. They were thus incessantly occupied during ten minutes. Their motions became then more languid, and, after being utterly exhausted, they fell in succession to the bottom of the hive, till every one of them was in a state of complete asphyxia. It is remarkable that, at this period, the temperature of the hive, which had been previously at 95° of Fahrenheit, suddenly cooled down to that of the external air. On opening the door and the top of the hive, and establishing a current of air through it, the bees were soon restored to animation.

Their mode of Ventilating the Hive.

It was proved by this experiment, that the air is renewed through the small opening which serves as a door to the hive. By suspending light substances near the entrance, the existence of different currents of air was rendered manifest. After much reflection, it occurred that the violent agitation of the wings might have some influence in procuring this renewal of air. This conjecture was confirmed by an experiment with a glass bell, to the aperture of which an apparatus was fitted, consisting of a small ventilator, which could be moved rapidly round by machinery. When the ventilator was set in motion, the air within could support the combustion of a candle for an unlimited time. Observation further showed, that some bees are actually always employed in the office of ventilating the hive; they vibrate their wings with great vigour and constancy, producing so rapid a movement of them, that they cannot be seen except in the two extremities of the arc of vibration, which is at least one of 90°. While thus imitating the actions of flying, they fasten themselves with their

feet to the floor of the hive, so that the whole effect of that impulse which, were they at liberty, would carry them forwards with considerable velocity, is exerted on the air, which is therefore driven backwards in a powerful current. Some bees occasionally perform these ventilating motions on the outside of the hive, near the entrance, but a still greater number are employed in this office within doors; sometimes twenty are thus occupied at once, and each bee continues its motions for a certain time, occasionally for nearly half an hour, and is then relieved by another, who takes its place. This is the occasion of that humming sound which is constantly heard from the interior of the hive when the bees are not in a state of torpidity. But it is often heard with even more than usual loudness in the depth of winter. The warmth of the sun's rays, however, always occasions an increased activity among the ventilating bees. The immediate cause of these actions is probably some impression made on their organs by the presence of vitiated air: for a bee may be made to ventilate itself, by placing near it substances which have to them an unpleasant odour, such as spirit of wine, or oil of turpentine.

Temperature of the Hive.

The connection between an active respiration and a high temperature is remarkably exemplified in bees, among which, in consequence of their collecting together in large numbers, the heat is not so easily dissipated, and admits also of being easily ascertained by the thermometer. Mr Hunter found it to vary from 73° to 84° of Fahrenheit: and Mr Huber observed it on some occasions to rise suddenly from about 92° to above 104°.

Progressive Motion.

Bees are well fitted, by their structure, for rapid flight through the air. They possess great muscular strength in proportion to their size, and their indefatigable activity in the different labours of the hive is truly astonishing. Aristotle and Pliny have pretended that, during high winds, they endeavour to steady their flight by holding a small stone with their feet, by way of ballast. This assertion has been shown, both by Swammerdam and Reamur, to be erroneous, in as far as it applied to the common bee; but there are other species, which build nests with stones and other hard materials, and which, while transporting them for this purpose, were probably mistaken for the honey-bee.

Sensitive Powers.

The physiology of the external senses must necessarily be very imperfectly understood, in a class of animals of a nature so remote from our own species. The infinite diversity of characters presented to us by the different tribes of insects, as well as of other animals, naturally suggest the idea that external objects produce, on their sentient organs, impressions widely different from what they communicate to ourselves. The notions we form of their senses must not only be liable to great inaccuracy, but must often be totally inadequate representations of the truth. A more fine organization, and more subtle perceptions, would alone suffice to extend the sphere of their ordinary senses to an inconceivable degree, as the telescope and the microscope have with us extended the powers of vision. But they possess, in all probability, other organs, appropriated to unknown kinds of impressions, and which must open to them avenues to knowledge of various kinds, to which we must ever remain total strangers. Art has with us supplied many elaborate modes of bringing within our cognizance some of the properties of matter, which nature has not immediately furnished us with the means of detecting. But who will compare our thermometers, electroscopes, or hygrometers, however elaborately constructed, with those refined instruments, with which the lower classes, and particularly insects, appear to be so liberally provided? The antennæ, which are so universally met with in this class of animals, are doubtless organs of the greatest importance in conveying impressions from without. Their continual motion, the constant use which is made of them in examining objects, the total derangement in the instincts of those insects which have been deprived of them, point them out as exquisite organs of more than one sense. To impressions of touch, arising from the immediate contact of bodies, they are highly sensible; but their motions evidently show that they are affected by objects at some distance. They are no doubt alive to all the tremulous motions of the surrounding air, and probably communicate perceptions of some of its other qualities. Composed of a great number of articulations, they are exceedingly flexible in every direction, and can readily embrace the outline of any body that the bee wishes to examine, however small its diameter, and of following all its movements. It is by means of these instruments that bees are enabled to execute so many works in the interior of the hive, from which the light must be totally excluded. Aided by these, it builds its combs, pours honey into its magazines, feeds the larvæ, and ministers to all their wants, which it discovers and judges of solely by this species of touch.

Functions of the Antennæ.

The antennæ appear also to be the principal means employed for mutual communication of impressions. The different modes of contact constitute a sort of language which appears to be susceptible of a great variety of modifications, and to be capable of supplying at once every species of information for which they have occasion. It is in this way alone that they satisfy themselves of the presence of their queen, or communicate to others the alarming intelligence that she has disappeared.

Vision.

The sense residing in the antennæ appears to be, on many occasions, supplementary to that of vision, which in bees, as in other insects, is less perfect than in the larger animals. During the night, therefore, they are chiefly guided in their movements by the former of these senses. This will sufficiently appear from observing by moon-light the mode in which the bees guard the entrance of the hive against the intrusion of moths which flutter in the neighbourhood. They act as vigilant sentinels, performing continual rounds near this important post, extending their antennæ to the utmost, and moving them alternately to the right and to the left. Woe to the unfortunate moth that comes within their reach. Aware of its danger, and of the defective sight of the bees, the moths adroitly avoid the slightest contact, and endeavour to insinuate themselves between the bees, so as to get unperceived in-

to the hive, where they riot upon the honey which they find.

If bees require full day-light for the exercise of vision, it must, at the same time, be acknowledged, that, when they are so assisted, they appear to enjoy this sense in great perfection. A bee will recognise its habitation from great distances, and distinguish it at once from many others in a numerous apiary. It passes through the air in a straight line towards its object with extreme rapidity. On quitting the hive, it flies towards the field which is most in flower; and as soon as it has determined on its course, it takes as direct a line as a ball issuing from a musket. When it has collected sufficient provision, it rises in the air to discover its hive, and then darts forward with the velocity of an arrow, and with unerring precision in its aim.

Perceptions of Temperature.

Their perceptions of heat and cold, which are generally referred to the sense of touch, appear to be extremely delicate. In several experiments of Huber's, the influence of the rays of the sun excited them to a vigorous action of the wings. It is well known, that great cold reduces them to a state of torpor, and inferior degrees of cold are evidently unpleasant to them. They show by their conduct that they are sensible of alterations in the state of the weather for some time before we can perceive them. Sometimes, when working with great assiduity, they will suddenly desist from their labours; none will stir out of the hive, while all the working-bees that are abroad hurry home in crowds, and press forward so as to obstruct the entrance of the hive. Often when they are thus warned of the approach of bad weather, we can distinguish no alteration in the state of the atmosphere. Gathering clouds sometimes produce this effect on them; but perhaps they possess some species of hygrometrical sense, unconnected with any impression of vision. It is alleged that no bee is ever caught in a sudden shower, unless from some cause it has wandered very far from the hive, or been disabled by some accident from returning to it. There is reason for thinking, however, that much exaggeration has prevailed in the statements of authors as to the extent of this kind of foresight. Huber supposes that it is the rapid diminution of light that alarms them, for if the sky be uniformly overcast, they proceed on their excursions, and even the first drops of a soft shower do not make them return with any great precipitation.

Taste.

Their taste is perhaps the most imperfect of their senses. They exert hardly any discrimination in the collection of honey from different flowers. They are not repelled by the scent or flavour of such as are extremely offensive to our organs, and scruple not to derive supplies from such as are highly poisonous. In some districts in America, it is well known that the honey acquires in this way very deleterious properties. The qualities of honey are, indeed, observed to vary much, according to the particular situation from which it is obtained. The most stagnant and putrid waters, as we have already noticed, are resorted to by bees with the same avidity as the purest. In their selection of flowers they are guided by the quantity of honey they expect to meet with, and in no respect by its quality. When the scythe has cut down all the flowers which before yielded them a plentiful supply, they discontinue their excursions, although the weather be in all respects propitious. Their smell must, therefore, be sufficiently acute to enable them to discover the presence of honey at great distances. Direct experiment has, indeed, proved this to be the case. Mr Huber found that they proceeded immediately towards boxes, which contained honey concealed from their view; and such, in fact, is the situation of the fluid of the nectaria in flowers. Some odours, especially the fumes of tobacco, and indeed all kinds of smoke, are highly obnoxious to them; this is the case, also, with the smell of oil of turpentine, alcohol, ammonia, the nitric and muriatic acids, and several other volatile chemical agents, upon receiving the impressions of which, they immediately set about ventilating themselves in the manner above described. But nothing excites their displeasure in a greater degree than the breath of the spectator; as soon as they feel which, they show signs of anger, and prepare to revenge it as an insult. The odour of the poison of their sting produces similar effects, exciting them to immediate rage and hostility.

Smell.

Although it is sufficiently clear that many insects possess the power of smell, yet the particular organ of this sense has never been accurately ascertained; and the opinions of naturalists have been much divided on this subject. These opinions have been supported more by argumonts drawn from the analogy of what happens in other classes of animals, than by any direct experiments on insects themselves. We know that, in all animals respiring by means of lungs, the organs of smell are placed at the entrance of the passages of the air; and it has often been concluded, that, in like manner, the stigmata, or the orifices of the air tubes, were the seat of this sense in insects. By others, the antennæ have been assigned as the organs, through which these impressions were conveyed to the sensorium. The experiments of Huber have proved that neither of these opinions is correct; and have satisfactorily shown, that in the bee this sense resides in the mouth itself, or in its immediate vicinity. Here, indeed, would be its proper station, if this faculty be intended, as we may reasonably suppose it to be, to apprize the individual of the qualities of the food, prior to its being eaten. When the mouth of the bee was plugged up with paste, which was allowed to dry before the insect was set at liberty, it remained quite insensible to the same odours, at which it had before manifested the strongest repugnance.

Hearing.

It is generally supposed that bees possess the sense of hearing. The common practice of making a loud noise by drums and kettles in order to attract a swarm is founded on this supposition. But the evidence is by no means conclusive; for we find that they are nowise disturbed by a loud clap of thunder, or by the report of a gun, or any other noises that may happen to arise around them. It is, however, certain, that they are capable of emitting a variety of sounds, which appear expressive of anger, fear, satisfaction, and other passions, and it would seem that they were even capable of communicating certain emotions to one another in this manner. Huber

observed, that the queens, during their captivity, sent forth a peculiar sound, which he supposes to be a note of lamentation. A certain cry, or humming noise from the queen, will strike with sudden consternation all the bees in the hive; and they remain for a considerable time motionless and stupified. Hunter has noticed a number of modulations of sound emitted by bees under different circumstances, and has instituted an inquiry concerning the means employed by them in producing these sounds, for an account of which we shall refer the reader to his paper in the *Philosophical Transactions*.

Instincts of Bees.

If the function of sensation in insects be involved in doubt and obscurity, the knowledge of those more interior faculties which are the springs of voluntary action is hid in still deeper mystery. Buffon refuses to allow bees any portion of intelligence, and contends that the actions we behold, however admirably they are directed to certain ends, are in fact merely the results of their peculiar mechanism. Other philosophers, such as Reaumur, have gone into the opposite extreme, and have considered them as endued with extraordinary wisdom and foresight,—as animated by a disinterested patriotism,—and as uniting a variety of moral and intellectual qualities of a higher order. The truth, no doubt, lies between these overstrained opinions; but it is extremely difficult to decide in what degree these respective principles operate in the production of the effects we witness. We have been too long in the habit of sheltering our ignorance of the causes of this class of phenomena, by referring them indiscriminately to what is called *instinct*, to submit to a cautious and patient investigation of the hidden springs of action. The term *instinct* should properly be regarded, not as denoting a particular and definite principle of action, whose operation we can anticipate in any new or untried combination of circumstances, but as expressive of our inability to refer the phenomena we contemplate to any previously known principle. Thus the actions which an animal performs in obedience to the calls of appetite, are not properly said to be instinctive; nor can the term be applied to actions, which are the consequence of acquired knowledge, and of which the object is with certainty foreseen by the agent. But when an animal acts apparently under a blind impulse, and produces effects useful to itself or to the species, which effects it could not have previously contemplated as resulting from those actions, it is then customary to say, that it is under the guidance of instinct, that is, of some unknown principle of action. It will be proper, therefore, to keep this distinction in view, in judging of the voluntary actions of the lower animals.

In no department of natural history is it more necessary to be aware of the proper import of the term instinct, than in studying the phenomena presented by the bee; for nowhere is it more difficult to discriminate between the regular operation of implanted motives, and the result of acquired knowledge and habits. The most striking feature of their history, and the one which apparently lays the foundation for those extraordinary qualities, which raise them above the level of other insects, is the disposition to social union. It may in general, indeed, be remarked, that animals which associate together so as to form large communities, display a higher degree of sagacity than those who lead a solitary life. This is especially observable among insects. The spider and *Formica leonis* may exhibit particular talents, or practise particular stratagems in the pursuit and capture of their prey; but their history is limited to a single generation, and embraces none of those interesting relations, which obtain between individuals composing the gregarious tribes, such as the ant, the wasp, and the bee. Among these we trace a community of wants and desires, and a mutual intelligence and sympathy, which lead to the constant interchange of good offices, and which, by introducing a systematic division of labour, amidst a unity of design, leads to the execution of public works on a scale of astonishing magnitude. The attachment of bees to their hive, which they defend with a courage and self devotion truly admirable; their jealousy of intruders; their ready co-operation in all the labours required for the welfare of the community; their tender care of their young; the affection and homage which they bestow on their queen, and which they manifest on all occasions in the most unequivocal manner,—imply qualities such as we could hardly persuade ourselves could animate a mere insect, on which we are in the habit of proudly looking down as placed in one of the lowest orders of created beings.

We shall content ourselves, at present, with these general observations, as the instances which serve to illustrate their moral and intellectual character belong properly to the history of the different processes they follow in the construction of their combs, the hatching and rearing of their progeny, and the mode of conducting their migrations. To these subjects, therefore, we shall now proceed: and in order to present the most connected and complete account of their economy, we shall begin the history from the period when a new swarm has just occupied a hive, and when all the arrangements for their habitation, and the construction of the cells in which their eggs and provisions are to be deposited, are yet to be effected.

Preparation of the Hive.

The first care of the labouring-bees, on their settlement in their new abode, is to clean it out thoroughly. While one set of bees is thus employed, another is distributed about the country, in order to procure the proper materials for blocking up the small holes and chinks of the hive, and for laying a firm foundation for the edifice, which is to be constructed within it. The substance which is principally employed in this preliminary stage is *Propolis*, a species of glutinous resin of an agreeable aromatic odour, and reddish brown colour, in process of time becoming darker, and acquiring a firmer consistence. According to the analysis of Vauquelin (*Mém. Soc. Agricult. Departem. Seine*), it is composed chiefly of resin, with a small proportion of wax, and of acid, and aromatic principles. It is soluble in alcohol, ether, and oils, both fixed and volatile; and tinges the solvent of a beautiful red colour. Cadet has since ascertained in it the presence of benzoic and gallic acids. Reaumur had not been able to dis-

Nature and Origin of Propolis:

cover from what plants the bees collect this substance. Riem asserts, that it is chiefly from pines and other trees of the fir kind. The recent observations of Huber have assisted in the solution of this question. On placing branches of the wild poplar tree before the hive, he found that the bees eagerly seized upon the varnish which exudes from the buds; and examining the chemical properties of this varnish, he identified it with the propolis, with which the inside of the hive is lined.

Mode of its Application.

The propolis adheres so strongly to the legs and feet of the bee which has collected it, that it cannot be detached without the assistance of its fellow labourers. For this purpose the bee that is loaded presents its legs to the workers in the hive, which carry off with their jaws this adhesive substance, and immediately apply it, while yet ductile, all round the interior of the hive, and particularly over all the projecting parts; hence its name, of Greek derivation, signifying *before the city*. In like manner all the foreign bodies that are introduced into the common habitation, and are too heavy to be removed, are covered over with this resinous substance. If a snail, for instance, should happen to introduce itself into the hive, after dispatching it with their stings, they encrust it over with propolis. Mr Knight has observed that, besides propolis, bees will occasionally carry home, and employ as cement, other substances, having the same glutinous properties. He frequently covered the decorticated parts of trees, on which he was making experiments, with a cement composed of bees-wax and turpentine; and in the autumn, has observed a great number of bees occupied in carrying off this substance. They detached it from the tree with their forceps, and the little portion thus obtained was then transferred by the first to the second leg, by which it was deposited on the thigh of the third, precisely in the same manner as the pollen of flowers is collected and transferred. Whilst the bees were employed in the collection of this substance, Mr Knight had many opportunities of observing the peaceful and patient disposition of them as individuals, which Mr Hunter had also, in some measure, noticed. When one bee had collected its load, and was just prepared to take flight, another often came behind it, and despoiled it of all it had collected. A second, and even a third load was collected, and lost in the same manner; and still the patient insect pursued its labour, without betraying any symptoms of impatience or resentment. When, however, the hive is approached, the bee appears to be the most irritable of all animals, and is animated with the most vindictive spirit against a public enemy, without displaying any peculiar hostility in the revenge of a private injury.

Construction of the Combs.

The next object of their labours is to prepare the combs, which are to be the receptacles for the eggs, with which the queen is pregnant, and which are now about to be laid. The material employed for this purpose is not propolis, but wax; the production of which, by secretion from a particular set of bees, who feed largely upon honey, was formerly explained. The bees are, for this purpose, actively employed in collecting honey, and in imparting it to their companions in the hive, who, when they have filled their crops with it, hang together in a thick cluster from the top of the hive, and thus remain in a state of inactivity for a considerable period. During this time, the secretion of wax is proceeding, and may be seen collected in laminæ under the abdominal scales, whence it is removed by the hind-legs of the bee, and transferred to the fore-legs, and from thence taken up by the jaws. In this operation, they are often assisted by their companions, who even directly seize upon the wax from under the abdomen of those who are before them. When a sufficient quantity of materials has thus been collected together, the process of building is commenced. But, in order to understand the subsequent operations, it is necessary to have a correct idea of the form of the cells which compose the combs. We shall, therefore, proceed to give some account of their structure when they have attained their perfect state.

Form of the Combs.

The combs of a bee-hive are formed into parallel and vertical strata, each of which is about an inch in thickness, the distances between the surfaces of each being about half an inch, an interval which serves for the passage of the bees over both surfaces. They generally extend the whole breadth of the hive, and often descend the whole length, from the top to the bottom. They consist altogether of thin partitions, which inclose hexagonal cells about half an inch in depth, and a quarter of an inch in diameter, opening on both surfaces of the comb, and closed by a partition common to those on both sides, and which occupies the middle distance between the two surfaces. This partition is not, however, a plane, but is composed of a collection of rhombs. Three, and sometimes four of these rhombs, inclined to one another at a certain angle, form the bottoms of each cell, which thus has the shape of a flattened pyramid, of which the basis is towards the mouth of the cell. The geometric form of each individual cell is, therefore, a hexagonal prism, terminated by a trihedral pyramid; the three sides of which pyramid are rhombs, which meet at the apex by their obtuse angles, and, forming oblique angles with the sides of the prism, truncate a portion of these, and convert them from rectangles, which they would be in a regular prism, into trapeziums. Of the two angles of these trapeziums, adjoining to the base of the pyramid, one must be acute and the other obtuse; the acute angle of one trapezium being next to the acute angle of the adjoining trapezium, and the obtuse angle being in like manner next to another obtuse angle of the preceding trapezium; so that, in going round the base, we meet with pairs of acute and of obtuse angles alternately succeeding each other. The two adjoining acute angles of the trapezia are adjoining to two of the terminal rhombs, which here present their acute angles; so that at these points a solid angle of four planes is formed, all the angles being acute. Each pair of obtuse angles of the trapezia, on the other hand, are adjacent to the obtuse angle of one of the rhombs only; thus composing a solid angle of three planes, of which the angles are all obtuse, and these two kinds of solid angles succeed one another alternately all round the base of the pyramid; there being three of each kind, and six in all. The axis of each cell coincides, not with

the axis of the cell on the opposite surface, but with one of its angles, so that each of the three obtuse angles, at the base of the terminal pyramid, corresponds to the central parts of three of the cells on the opposite side; and each of the sides of the pyramid, which closes a cell on one side, contributes, in part, to the closing of three of the cells on the opposite side. We may easily satisfy ourselves that this is the case, by piercing the centres of each of the three planes which close the bottom of a cell, with a small pin, when, on turning the comb, the three pins will be found to have passed into three different cells on the opposite side.

Geometric Properties of the Cells.

A structure of this kind is obviously the one of all others calculated to afford the greatest space for each cell, with the same expence of materials. It is easy to perceive, in the first place, that, in a plane surface, when a number of small spaces are to be divided by partitions, the hexagonal form is the one which comprehends the largest space compatible with the extent of the lines which inclose them. For the equilateral triangle, the square, and the regular hexagon, are the only regular forms that admit of being joined together in the same plane without leaving interstices; and the proportion of the area to the periphery in every polygon, increases as the figure consists of a greater number of sides, and is therefore greater in the hexagon than in any of the other two. The truth of this proposition was perceived by Pappus, and even its application to the subject of the honeycomb was made by that ancient geometrician. But the determination of the form and inclination that should be given to the partitions which close the bottoms of the cells, and which may of course belong equally to those on both sides of the comb, is a problem much more complicated and difficult of solution. It has exercised the skill of several modern mathematicians of great eminence; and has generally been resolved by the assistance of the infinitesimal calculus, or the methods of maxima and minima. A mistake has sometimes been committed in supposing that the capacity of the cells would be affected by varying the inclination of the partitions, whereas, if abstraction be made of the thickness of these partitions, all the space which is gained on the one side must be obtained at the expence of the space on the other, and the sum total will therefore remain the same. This error has been pointed out by Le Sage of Geneva, and also by others. The whole question, therefore, resolves itself into that of the form producing the greatest saving of materials. Kœnig, the pupil of the celebrated Bernouilli, calculated that the angles of the rhombs, which should answer this condition, must be 109° 26′, and 70° 34′. Cramer, professor of mathematics in the University of Geneva, has given a very elegant demonstration of this problem, from which it results that the obtuse angle of the rhomb must be such, that its half has for its tangent the square root of 2. This is the case with the angle 54° 44′ 8″; the two angles of the rhomb are therefore 109° 28′ 16″, and 70° 31′ 44″. It follows, also, that the two diagonals of this rhomb are to one another in the same proportion as the side and diagonal of a square, that is, as 1 to 1.41421356237, &c. It is also another consequence from the same data, that the angles of the trapezia forming the sides of the hexagonal prism adjacent to the rhombs, are precisely equal to those of the rhombs themselves, and that the solid angle formed at the apex of the pyramid, and which is composed of those equal obtuse angles, is precisely equal to each of the three angles at the base, which are also formed of three obtuse angles. It is also true that these are the only angles which will give this perfect equality. Maraldi had already made the same remark; and assuming this principle of the equality of the angles as the basis of this reasoning, had calculated them on this hypothesis, making them 109° 28′ and 70° 32′, which is nearly accurate. To the same author we are indebted for the comparison of the results of theory with fact, by the admeasurement of the actual angles of the honeycomb; these he states to be about 110° and 70°, which is as near an agreement with theory as could well be expected.

Boscovich, who has also given a solution of the same problem, conceives that the equality of inclination of the planes gives greater facility to the construction of the comb, and might, therefore, be a motive of preference, independently of the greater economy of wax. Maclaurin has exercised his abilities in resolving this problem, and has demonstrated, by simple geometry, that the most advantageous form is that which results from the supposed equality of the three plane angles forming the solid angles at the base. He estimates the saving of wax by partitions so constructed, above what would be required for a flat partition, at one-fourth of the wax, which would be wanted to complete the truncated sides of the cells, so as to form them into rectangles. L'Huilleir, in the *Memoirs of the Berlin Academy*, has given a demonstration which is remarkable for its simplicity, and for its involving none but elementary propositions; he values the economy of wax at $\frac{1}{51}$ of the whole wax employed. Le Sage, as appears from the life of that philosopher by Professor Prevost, has shown that this celebrated problem reduces itself to the finding the angle at which two planes with a given inclination (such as 120°) can be cut by a third plane, so as to make all the angles resulting from the section equal to one another.

But a more essential advantage than even the economy of wax results from this structure, namely, that the whole fabric has much greater strength than if it were composed of planes at right angles to one another; and when we consider the weight they have to support when stored with honey, pollen, and the young brood, besides that of the bees themselves, it is evident that strength is a material requisite in the work.

It has often been a subject of wonder how such diminutive insects could have adopted and adhered to so regular a plan of architecture, and what principles can actuate so great a multitude to co-operate by the most effectual and systematic mode in its completion. Buffon has endeavoured to explain the hexagonal form by the uniform pressure of a great number of bees, all working at the same time, exerted equally in all directions in a limited space; and illustrates his theory by supposing a number of similar

Buffon's Theory of the Formation of the Comb.

cylinders compressed together, and taking the form of hexagonal prisms by the uniform expansion of each. The analogy of the forms produced by the law of crystallization,—of the figures assumed by various parts in the animal and vegetable world, such as the skin of the bat, the inner coat of the second stomach of ruminant quadrupeds,—is also adduced by this captivating, but superficial writer, in support of his argument. However plausible this theory may at first sight appear, it will not stand the test of a more serious examination. The explanation he has attempted applies no farther than to the inclination of the sides of the cells; but he did not take into account, perhaps from not having studied the subject mathematically, the inclinations and forms of the planes which close each cell, and so curiously conspire on both sides to serve a similar office, while they at the same time accurately fulfil a refined geometrical condition. But it is sufficient confutation of the whole theory to show, that it is directly at variance with the actual process employed by the insects in the construction of their combs.

Mode of their Construction.

It might be supposed that bees had been provided by nature with instruments for building of a form somewhat analogous to the angles of the cells; but in no part, either of the teeth, antennæ, or feet, can any such correspondence be traced. Their shape in no respect answers to that of the rhombs, which are constructed by their means, any more than the chisel of the sculptor resembles the statue which it has carved. The shape of the head is, indeed, triangular, but its three angles are acute, and different from that of the planes of the cells. The form of the plates of wax, as they are moulded in the pouches into which this substance is secreted, is an irregular pentagon, in no respect affording a model for any of the parts which compose the honeycomb. Hunter, observing that the thickness of the partition was nearly equal to that of the scale of wax, thought that the bees apply these scales immediately to the formation of the partition, by merely cementing them together. Reaumur, notwithstanding the use of glass hives, had not been able to discover the mystery of their process of architecture; but inferred, from what he saw, that the wax was rejected from the stomach in the form of a white frothy liquor. No naturalist, indeed, prior to Huber, had been able to follow these insects in their labours, on account of their crowding together in a thick mass while they are building; but the expedients resorted to by that ingenious philosopher have unfolded the whole process, which he has given with great detail in the second volume of his *Observations sur les Abeilles.* Huber witnessed the whole of their actions, and saw that each bee drew out, with its hind feet, one of the plates of wax from under the scales where it was lodged, and, carrying it to the mouth in a vertical position, turned it round, so that every part of its edge was made to pass in succession under the cutting edge of the jaws; it was thus soon divided into very small fragments, while at the same time a frothy liquor was poured upon it from the tongue, so as to form it into a perfectly plastic mass. This liquor gave the wax a whiteness and opacity which it did not possess originally, and rendered it at the same time tenacious and ductile. A quantity of wax thus prepared for use is accumulated, and applied to further the work in the manner we are presently to describe.

But, in considering the process by which the comb is formed, a circumstance should be pointed out, which seems not to have been particularly noticed by any author except Huber; and yet it is one of essential importance in studying their process of architecture,—it is, that the first row of cells, on either side, are of a form very different from that of the subsequent rows. As they take their origin from a plane surface, two of the sides necessary to complete the hexagon are cut off by this plane, so that the general form of the orifice is pentagonal; and the bottom of the cells on one side are composed of two equal rhombs only, and, on the other side, of two trapezoidal planes, with one rhomb. Such a modification of shape was necessary, in order to prepare the way for the regularly formed cells which were to follow.

The foundations of the combs are laid by the bees raising a solid block or plate of wax, of a semicircular form. In this they scoop out a small vertical channel, of the size of an ordinary cell. The sides of this channel are then strengthened by additions of wax. On the opposite side, two other channels are formed, one on each side of the plane opposite to the former channel. The extremities of these channels, which at first present a curved outline, are then fashioned into straight walls, forming an angle at each vertex. The bottom of each cell being thus sketched out, the design is completed by raising walls round the sides. Different bees generally work on the opposite sides at the same time, and appear to have some perception of the thickness of the partitions, and of the situation of the opposite walls, in which they are perhaps guided by slight prominences, occasioned by the depressions which correspond to them on the other side; and they scrape off the wax in those places where its thickness is greatest; that is, where the bees on the other side had accumulated materials. In this way, then, in constructing the successive rows, the axis of each cell will be found to occupy the most retiring parts of the partition, and will be opposite to the junction of three of the opposite cells.

Soon after the bees have completed the foundations, and constructed a few of the cells of the central comb, they begin two others, one on each side, at the proper distance, and in this manner continue to form others in succession, in proportion as the former are advanced. Their object, at first, seems to be, to extend the surface of the work, so as to admit of the greatest possible number of workers being employed at one and the same time. In this way, then, the work proceeds from all points at once, new cells being begun before the former are completed, so that the whole comb, while it is in progress of construction, has a semi-lenticular shape, broader at the top, and tapering below and towards the sides. It extends downwards, however, more rapidly than in any other direction, and its surfaces do not become parallel to each other, till the last stage of the building process. When this is completed, the whole is further strengthened by an additional coating

Bee.

of propolis, round the margin of all the cells; and the junctions of every plane, both of the sides and bottoms of the cells, are also soldered together by a lining of the same substance. The edges of the combs are also secured in their situations by being glued to the side of the hive, and supported by fresh abutments of propolis. Sometimes a mixture of wax and propolis, manufactured by the bees themselves, is employed as the cementing material. The first coating of this compound substance is denominated *Commosis* by Pliny, and described as having a bitter taste; the second, or the *Pissoceros* of the same author, is stated to be of a thinner consistence, and more adhesive than the former; while the third substance or propolis is completely solid.

The cells recently constructed are perfectly white, but in a short time they are found of a yellow tint, which becomes gradually deeper, and when very ancient gives them a dark brown cast. It is therefore easy to distinguish in a hive the successive periods of formation of different portions of the combs. From the researches of Huber, it appears, that these variations of colour are not owing to any changes in the wax itself, but to additional coatings of a peculiar varnish, consisting of propolis and a colouring matter. The latter differs materially from propolis, being wholly insoluble in alcohol. It loses its colour by the action of nitric acid, or the light of the sun. Its origin has not yet been discovered; nor has the mode in which it is applied been clearly made out; although Huber presumes, from his observations, that they spread it by means of their mandibles, which he has seen them rub against the sides of the cells, while they acquired a yellow colour from the operation.

Different Kinds of Cells.

Such is the general outline of the architectural labours of the bee. A number of modifications are however met with, adapting them to various purposes and to new circumstances. The cells are required to be of different sizes for the reception of different sorts of eggs and larvæ. The smallest, which are also the most numerous, are appropriated to the eggs of the working-bees; a larger sort receive those of the males; and a small number of very large cells are destined for the education of the young queens, and are therefore called royal cells. The first set are generally $5\frac{1}{3}$ lines in depth, and $2\frac{1}{2}$ in diameter; the second are from 7 to $7\frac{1}{2}$ lines in depth, and $3\frac{2}{3}$ths in diameter; while the royal cells are above one inch deep, one-third of an inch wide, and their walls about one-eighth of an inch in thickness. Other cells, again, are set apart as magazines of honey, or of pollen; they are made twice as deep as the common cells, and their axes are inclined to the horizon, so that their mouths are in the highest part, and their liquid contents may be more easily retained. When these are filled, they are closed up by the bees with a wall of wax, and opened only when necessity requires.

The regularity of the cells is often disturbed in consequence of the admixture of rows of larger cells with those of smaller dimensions; but the pyramidal partitions are adapted by successive gradations to these changes; so that in many rows of what may be called cells of transition, the bottom

Cells of Transition.

presents four planes instead of three, two being trapeziums, and the other two irregular hexagons. These irregularities are met with chiefly in the combs most distant from the central one. When an abundant supply of honey induces them to lay up a large quantity in store, they build up for this purpose the walls of common cells so as to give them a greater depth. The royal cells are often raised from the ruins of a number of other cells, which are destroyed to make room for them; they are usually built on the edge of some of the shorter combs, and often in the very centre of the hive. Sometimes there are but three or four of them; at other times eleven, or even fourteen, have been counted in the same hive. They are formed of a mixture of propolis and wax; their form is oblong, resembling that of a pear; their position is always vertical, so that when they arise from amidst other cells, they are placed against the mouths of those cells, and project beyond the common surface of the comb. They are perfectly smooth on the inner surface; while their outer side is covered with a kind of hexagonal fretwork, as if they were intended for the foundation of regular cells.

Deposition of the Eggs.

As soon as a sufficient number of cells have been constructed, the queen begins to deposit her eggs. In those that have been impregnated the preceding year, the oviducts begin to swell early in the spring, so that by the month of March they are ready to come forth. The queen-bee is, therefore, the earliest breeder of any insect we are acquainted with. But the young queens are capable of laying eggs thirty-six hours after impregnation. It appears to be now well ascertained by the experiments of Huber, that she is aware of the nature of the eggs she is laying, and deposits each in the kind of cell adapted to receive it. She may be seen examining attentively the capacity of the cell before laying her egg. She passes thus from one cell to another, allowing herself hardly any interval of repose. She commonly lays two hundred eggs in a day; but if the weather be warm, and vegetation luxuriant, she will lay a much greater number. The cold of autumn suspends this process. The eggs first produced are those of labourers, and their deposition continues for ten or twelve days, during which interval, the working-bees are busily employed in constructing the larger cells. The queen next acquires a considerable increase of size, so as to walk with difficulty. She then lays male eggs in the large cells, during a period of from sixteen to twenty-four days. They are less numerous than the former eggs, in the proportion of one to thirty.

These industrious insects now set about constructing royal cells; and the queen-bee, having finished her deposition of male eggs, begins again to lay those of the common bees; and finding royal cells open for their reception, deposits a single egg in each, but only at intervals of one or two days; the common cells receiving those laid in the meantime. When the hive is not sufficiently numerous, or the season has been unproductive, no royal cells are formed; and the education of a queen is not attempted.

Nourishment of the Larvæ.

As soon as the eggs are deposited, the bees eagerly seek for that species of nourishment on which the

Bee.

larva is to be fed. This consists of pollen, with a proportion of honey and of water, which is partly digested in the stomachs of the nursing bees, and which is made to vary in its qualities according to the age of the young. Pollen is afforded by flowers in the spring in such abundance that the bees of a single hive will often carry home above a pound of this substance in one day. The eggs of bees are of a lengthened oval shape, with a slight curvature, and of a bluish white colour. They are hatched without requiring any particular attention on the part of the bees, except that of keeping up a proper temperature; in which case, three days are sufficient for the exclusion of the larva. The larva has the appearance of a small white worm without feet, which remains generally coiled up at the bottom of the cell. The nursing bees feed it with great assiduity, with the kind of jelly above described, and in every respect exhibit the greatest attachment for them. Mr Hunter says that a young bee-maggot might easily be brought up by any person who would be attentive to feed it. It may be seen opening its two lateral pincers to receive the food, and then swallowing it. As it grows up, it casts its cuticle, like the larvæ of other insects. In the course of five or six days, it has attained its full size, and nearly fills the cell in which it is lodged: it now ceases to eat, and the bees close up its cell with a covering of wax, or rather consisting of a mixture of wax and propolis, which they possess the art of amalgamating together. During the next thirty-six hours, the larva is engaged in spinning its cocoon; and in three days more, it is converted into the state of pupa or chrysalis. In this state it is perfectly white, and every part of the future bee may be distinguished through its transparent covering. In the course of a week, it tears asunder its investing membrane, makes its way through the outer wall of its prison, and emerges in its perfect form. Reckoning from the time that the egg is laid, it is only on the twentieth day of its existence that this last metamorphosis is completed. No sooner has it thus emancipated itself, than its guardians assemble round it, caress it with their tongues, and supply it plentifully with food. They clean out the cell which it had been occupying, leaving untouched, however, the greater part of the web, which thus serves to bind together still more firmly the sides of the comb. The colour of the bee, when it quits the cell, is a light grey; it requires two days before it can attain sufficient strength for flying. The metamorphoses of the male-bee follow the same progress, but require a few days longer for their completion, occupying about twenty-four days from the time of the egg being laid, to the attainment of the perfect state.

Process of rearing the Queen-Bee.

The eggs deposited in the royal cells are precisely similar to those of the working-bees, and might be substituted the one for the other. The larva arises from it precisely in the same manner, and does not differ from the larva of the workers. But the attention of the nursing bees is more incessantly bestowed on them; they are supplied with a peculiar kind of food, which appears to be more stimulating than that of ordinary bees. It has not the same mawkish taste, and is evidently acescent. It is furnished to the royal larva in greater quantities than it can consume, so that a portion always remains behind in the cell, after their transformation. The growth of the larva, and the development of all its organs, are very much accelerated by this treatment; so that in five days, it is prepared to spin its web; and the bees enclose it by building up a wall at the mouth of its cell. The web is completed in twenty-four hours; two days and a half are consumed in a state of inaction, and then the larva transforms itself into a pupa. It remains between four and five days in this state; and thus, on the sixteenth day after the egg has been laid, it has produced the perfect insect. When this change is about to take place, the bees gnaw away part of the wax covering of the cell, till at last it becomes pellucid from its extreme thinness. This must not only facilitate the exit of the fly, but may possibly be useful in permitting the evaporation of the superabundant fluids.

Rivalship of the Queens.

But the queen-bee, although perfectly formed, is not always at liberty to come out of her prison; for if the queen mother be still in the hive, waiting a favourable state of the weather to conduct another swarm, the bees do not suffer the young queens to stir out, they even strengthen the covering of the cell by an additional coating of wax, perforating it with a small hole, through which the prisoner can thrust out its trunk, in order to be fed by those who guard it. The royal prisoners continually utter a kind of plaintive song, the modulations of which are said to vary. One consequence of their detention is, that they are capable of flying as soon as they are set at liberty. But the motive of this proceeding, on the part of the bees who guard them, is to be found in the implacable hatred which the old queen bears against all those of her own sex, and which impels her to destroy without mercy all the young queens that come within her reach. The working bees are, on this account, very solicitous to prevent her even approaching the royal cells, while there is any prospect of a swarm being about to take place. They establish themselves as a guard around these cells, and, forgetting their allegiance on this occasion, actually beat her off as often as she endeavours to come near them. If, on the other hand, the swarming season is over, or circumstances prevent any farther swarms from being sent off, the bees do not interpose any obstacle to the fury of the old queen, who immediately begins the work of destruction, transfixing with her sting, one after the other, the whole of the royal brood, while they are yet confined in their cells. It is observed by Huber, that the royal larvæ construct only imperfect cocoons, open behind, and enveloping only the head, thorax, and first ring of the abdomen; and conceives that the intention of nature in this apparent imperfection, is that they may be exposed to the mortal sting of the queen, to whom they may be given up as a sacrifice.

When the old queen has taken her departure along with the first swarm, the young queens are liberated in succession, at intervals of a few days, in order to prevent their attacking and destroying one another, which would be the infallible consequence of their meeting. This exterminating warfare is

prevented by the vigilance of the bees who guard them, so long as new swarms are expected to take place. When a young queen is liberated, she is, like others of her sex, anxious to get rid of her rivals, and even at that early age seeks to destroy her sisters, who are still confined in the other royal cells; but as often as she approaches them she is bit, pulled and chased without ceremony by the centinels. But when the season is too far advanced for swarming, or when the hive is too much exhausted in its population by the swarms that have already been sent off, they no longer interfere in preserving peace, and the first that acquires her liberty proceeds to the massacre of all her rivals. If two or more queens should happen to issue out at the same moment, they mutually seek each other, and fight till one is killed; and the survivor is immediately received as the sovereign of the hive. The bees, far from seeking to prevent these battles, appear to excite the combatants against each other, surrounding and bringing them back to the charge when disposed to recede from each other; but when either of the queens shows a disposition to approach her antagonist, all the bees forming the clusters instantly give way to allow her full liberty for the attack. The first use which the conquering queen makes of her victory is to secure herself against fresh dangers by destroying all her future rivals in the royal cells; while the other bees, who are spectators of the carnage, share in the spoil, greedily devouring any food which may be found at the bottom of the cells, and even sucking the fluid from the abdomen of the pupæ before they toss out the carcasses.

Impregnation.

The impregnation of the queen-bee was formerly involved in the deepest obscurity, and has given rise to a multitude of very fanciful opinions. Some have denied that any intercourse with the male was necessary for the fecundation of the eggs. Swammerdam supposed that the mere effluvia proceeding from the males, where they were collected in clusters, was sufficiently active to produce this effect, by penetrating the body of the female. Huber proved, by a decisive experiment, that no such consequence resulted from these effluvia. Maraldi imagined that the eggs were fecundated by the drones, after being deposited in the cells, in the same way that the spawn of fishes is rendered prolific by the milters. Mr Debraw of Cambridge, in a paper published in the *Philosophical Transactions*, of which an account is given under the article Bee, in the *Encyclopædia*, fancied that he had seen the milt-like fluid in the cells. But this appearance has been shown by Huber to be a mere optical illusion, arising from the reflection of light at the bottom of the cell. When the males are excluded from the hive, the queen is as fertile, and the eggs as prolific, as when they are present. Hattorff supposed that the queen is capable of impregnating herself; an opinion which was supported by Schirach and Wilhelmi, and was even favourably received by Bonnet, as it in some measure accorded with his discoveries respecting the Aphis, of which our readers will find an account in the article Aphis. (See *Encyclopædia.*) Linnæus was of opinion that an actual union between the sexes took place, and Reaumur fancied that he had seen this happen within the hive. There is, however, great reason to think that he was mistaken. Huber has clearly proved that the queens are never impregnated as long as they remain in the interior of the hive; and, if confined within it, continue barren, though surrounded by males. It is only during her flight, at a considerable height in the air, that the male has complete access to her so as to effect the impregnation. In half an hour the queen-bee returns to the hive with unequivocal proofs of the intercourse that has taken place, for she has in fact robbed the drone of the organs concerned in this operation; and the drone, thus mutilated, is left to perish on the ground. From its being necessary that the queen should fly to a distance in order to be impregnated, Huber infers the necessity of a great number of drones being attached to the hive, that there may be a sufficient chance of her meeting one of them during her aërial excursion.

Preparation for Swarming.

We are now to direct our attention to the migrations of bees, by which new colonies, similar to that which had originally peopled the parent hive, are founded. The final causes of this phenomenon are sufficiently obvious; but it does not so clearly appear to what circumstances it is immediately owing. The increasing population of a hive probably occasions inconvenience from the want of room, the increase of heat, and the greater vitiation of the air; inconveniences which become still more serious as the summer advances. The spring is accordingly the commencement of the swarming season; no swarm, indeed, will ever take place while the weather is cold, nor until the hive is well-stocked with eggs of every kind. The queen-bee, in consequence of the great number of eggs she has been laying, is now reduced to a more slender shape, and is well fitted for flight. Her aversion for the royal brood, which she seems to foresee will in no long time become able to dispute the throne with her, and the vain attempts she makes to destroy them in the cradle, in which she is invariably repelled by the bees who guard them, produce in her a constant restlessness and agitation, which, as Huber represents it, rises to a degree of delirium. This frenzy, from whatever cause it may originate, is communicated to the workers; they may be seen hurrying to and fro in the combs, with evident marks of impatience; the heat of the hive is increased by their tumultuous movements; it sometimes rises suddenly, on these occasions, from 92° to above 104°. A general buzz is heard throughout the hive. This state recurs from time to time, for some days before the swarm is actually on the wing; and the interval is occupied in making preparations for the approaching expedition. Provisions are collected in greater quantity by the working-bees. Mr Hunter killed several of those that came away, and found their crops full, while those that remained in the hive had their crops not near so full. Scouts are sent out to look for a proper habitation. Mr Knight, in the *Philosophical Transactions*, gives us a curious account of his observations on their manœuvres in this respect. In the cavity of a hollow tree, which, by the application of a board, had been fitted up for the reception of the swarms, he constantly ob-

Bee.

served "that, about fourteen days previous to their arrival, a small number of bees, varying from twenty to fifty, were every day employed in examining, and apparently in keeping possession of the cavity; for if molested, they showed evident signs of displeasure, though they never employed their stings in defending their proposed habitation. Their examination was not confined to the cavity, but extended to the external parts of the tree above; and every dead knot particularly arrested their attention, as f they had been apprehensive of being injured by moisture, which this might admit into the cavity below; and they apparently did not leave any part of the bark near the cavity unexamined. A part of the colony, which purposed to emigrate, appeared in this case to have been delegated to search for a proper habitation; and the individual who succeeded must have apparently had some means of conveying information of his success to others; for it cannot be supposed that fifty bees should each accidentally meet at, and fix upon the same cavity, at a mile distant from their hive, which Mr Knight has frequently observed them to do, in a wood where several trees were adapted for their reception; and, indeed, he observed, that they almost uniformly selected that cavity, which he himself thought was the best adapted to their use. It not unfrequently happened, that swarms of his own bees took possession of these cavities, and such swarms were in several instances followed from his garden to the trees; and they were observed to deviate very little from the direct line between the one point and the other, which seems to indicate that those bees, who had formerly acted as purveyors, now became guides."

Departure of the Swarm.

On the day on which the swarm quits the hive, few of the workers roam to any distance, but several are seen performing circles in the air round the hive. The noise is on a sudden hushed; and all the bees enter the hive; this silence announces their immediate departure. A few workers appear at the door, turn towards the hive, and striking with their wings, give, as it were, the signal for flight. All those who are to accompany the expedition rush towards the door, and issue forth with wonderful rapidity, rising in the air and hovering for sometime, as if in order to wait for the assemblage of the whole troop. Then, following the motions of the queen, they settle wherever she alights, forming a dense cluster around her. Sometimes, from weakness, or other cause, she returns back to the hive, and is immediately attended thither by the rest. But if the weather be fine, the expedition is only deferred for one or two days, and again takes its departure. If their return be owing to the loss of their queen, they remain a fortnight or longer before the attempt to migrate is renewed, and then the swarm is much larger than before, which renders it probable that they have waited for the queen that was to go off with the next swarm. Sometimes when every thing indicates an approaching emigration, the passage of a cloud across the sun will suspend all their operations, and the previous bustle gives place to a state of perfect calm. But, if the day be not far advanced, the breaking out of sunshine will renew the commotion, and determine the moment of actual flight.

The swarm having rested for some time on the first landing-place, and collected the whole of its numbers, soars again in the air, keeping in a close phalanx, and directing its course with great velocity to the spot which their guides had selected; giving out, at the same time, a loud and acute toned hum by the action of their wings.

Succession of Swarms.

The parent hive, thus deserted by its queen and a large proportion of its inhabitants, is busily occupied in repairing its loss. The bees which remain quietly pursue their labours; the young brood, soon arriving at maturity, quickly fill up every deficiency; and young queens, being allowed their liberty, one after the other, conduct in their turns new swarms, in the same manner as the first. The second swarm is not sent off till after the space of from five to ten days after the first. The following swarms succeed quicker to each other, but consist of smaller numbers than the earlier ones. If it happen that two queens are found in a swarm, either the swarm divides itself into two, and have separate destinations, or a single combat between the queens decides on which of them the empire is to devolve. Sometimes, indeed, they appear not to perceive each other, and the parties belonging to each construct separate combs within the same hive; but no sooner do these combs come in contact, and thus give occasion to the queens meeting each other, than the contest begins, and it does not terminate but by the death of one of the rival queens. Successive swarms are sent off so long as the increase of population admits of it, and the numbers thus produced in a season depends on a variety of circumstances, such as the abundance of flowers, and the warmth of the climate, and the capacity of the hive. Bosc, while he was French consul in Carolina, found a hive in the woods which had been robbed of its wax and honey by the negroes; he contrived to convey the bees in his hat to a hive in his garden; he obtained from this hive eleven swarms before the end of autumn; and these again afforded him the same number of secondary swarms, so that, by the end of the year, he had twenty-two hives stocked from the one he had thus saved from destruction. In this country, a hive commonly sends off only two, and sometimes three swarms in the course of the summer.

Massacre of the Drones.

Very few drones accompany the new colonies; so that almost all those produced in the spring remain in the hive. But when the queens are impregnated, and no new swarms are about to take place, the workers, who had till then suffered them to live unmolested in the hive, are on a sudden seized with a deadly fury towards them, and a scene of carnage ensues. This usually happens in July or August. They chase their unhappy victims in every quarter, till they seek a refuge at the bottom of the hive, where they collect in crowds, and are indiscriminately, and without a single exception, massacred by the working-bees, who, with implacable fury, transfix them with their stings, and throw the dead bodies out of the hive. So great is their antipathy to all the race of drones, that they destroy, at the same time, the male eggs and larvæ, and tear open the cocoons of their pupæ, in order to devote them to one common destruction. This sacrifice of the

males is not, however, the effect of a blind and indiscriminating instinct; for if a hive be deprived of its queen, the massacre does not take place, while the hottest persecution rages in all the surrounding hives. In this case the males are allowed to survive one winter.

Provision for the Winter.

Having thus got rid of the useless mouths, which consumed, without any advantage to the public, a large portion of their provisions, the bees spend the remainder of the summer in collecting stores of honey and of pollen for the ensuing winter. Their gleanings are now less abundant than in the spring, and require more labour in the search and collection. But at this season, the leaves of many kinds of trees, which are covered in the morning with a saccharine fluid that transudes through them, furnish them with a species of nourishment, which, though of very inferior quality to the fluid of the nectaria, still contributes to their support. Fruit is also attacked by bees, after the cuticular covering has been broke through by birds or snails. They also find nutriment in the *Honey-dew*, which is an excrementitious fluid from the Aphis. (See that article). Often, however, these resources fail, and the hive is threatened with famine. On these occasions, the distressed bees often betake themselves to plunder. Spies are sent out to examine the neighbouring hives; allured by the smell of honey, they examine the appearance and strength of its possessors; and, selecting the weakest hive as the object of attack, they begin a furious onset, which costs great numbers their lives. If the invaders should fail in their attempt to force the entrance, they retreat, and are not pursued by those whom they have assailed; but if they succeed in making good the assault, the war continues to rage in the interior of the hive, till one party is utterly exterminated; reinforcements are sent for by the invading army, and the bees from the neighbouring hives often join the assailants and share in the plunder. In a short time the whole of the enemy's magazines are completely emptied. If on the other hand, the invaders should be defeated, the successful party is by no means safe from the attacks of the bees from other hives, if any of them should chance to have mingled in the fray, and especially if they have once penetrated as far as the magazines, for in that case they are sure to return, accompanied with a large reinforcement, and the unfortunate hive that has been once attacked, ultimately falls a sacrifice to these repeated invasions.

Mutual Depredations.

The close of autumn puts a period to their labours abroad. They then live on the provisions they have amassed, till the cold of winter reduces them to a torpid state; from which they awake on the return of vernal warmth, and renew the same circle of labours. Sometimes the strong light reflected from the snow during a clear sunshine, deceives them with the appearance of warmth, and some bees are tempted to issue forth in order to collect provisions. All who thus venture out perish by the cold in a few minutes.

Duration of Life.

Bees seldom die a natural death. They are at all times exposed to a variety of accidents, which thin their numbers; so that the average duration of their lives does not exceed one year. We may conclude that the whole generation is renewed in that space of time, from the results of experiments which have been tried of marking all the individuals of a hive in the spring, when it was found that none were in existence the next season. They are the natural prey of a number of quadrupeds, birds and insects; many are overtaken by stormy weather, or fly to too great a distance, and never find their way back again to the hive; others are benumbed by cold; and numbers perish in battle with others of their own species, or lose their lives by being unable to withdraw the stings which they have employed against their enemies. The fecundity of the queen-bee is, however, adequate not only to repair these losses, but to multiply the population in a very high progression. It is computed that in France a single queen will lay from 30 to 60,000 eggs; this however varies according to the climate; for in Carolina and the West Indies, they are known to produce at least three times this number. A single intercourse with the male is sufficient for the fecundation of all the eggs which the queen lays for at least two years, as has been proved by Huber; but its influence probably extends to all the eggs which the queen may lay during the rest of her life. The same queen has been observed to conduct swarms for two successive years; but the natural period of their lives is not known with any certainty. The ancients supposed it to be seven years, but Féburier suspects, that, like the males, they are destroyed by the labourers, when they have fulfilled their destination; for he was witness to an attack made by six labourers on a queen, whom he rescued with difficulty. Mr Hunter observes, that, judging from analogy, a bee's natural life is limited to a certain number of seasons; for he conceives that no individual insect of any species lives one month longer than the others of the same species. In the bee, one might suppose the period of life to be equal to the time that a hive can last; but this is not a necessary consequence, since they keep up a succession of generations. The comb of the hive may be said to be the furniture and storehouse of the bees, which by use must wear out; but, independently of this, it will, in time, become unfit for use, by the accumulation of cocoons, together with the excrements of the maggots, which are never removed. The former, indeed, lines the whole cell, top, sides and bottom; and may be distinguished from the cocoons of former maggots, that have been hatched in the same cell, by a portion of dried excrement, which is interposed between them, at the bottom of the cell. Mr Hunter has counted above twenty different linings in one cell, and found the cell about one quarter, or one-third filled up. A piece of comb so circcumstanced, when boiled for the wax, will keep its form, and the small quantity of wax is squeezed out at different parts, as if squeezed out of a sponge, and runs together in the crevices; while a piece of comb that never has been bred in, even of the same hive, melts almost wholly down. Hence, the combs can only last a certain number of years. However, to make them last longer, the bees often add a little to the mouth of the cell, which is seldom done with wax alone, but with some sort of mixture; and they sometimes

Fecundity of the Queen-Bee.

Durability of the Combs.

Bee.

cover the silk lining of the last chrysalis; but all this, observes Mr Hunter, makes such cells clumsy, in comparison to the original ones.

We have thus given an account of the principal facts in the history of bees, as far as they relate to the usual or natural condition of these insects. We shall conclude with the relation of several curious phenomena, which they exhibit under particular and unusual circumstances, in which accident, or the designs of the experimenter, may have placed them.

What happens when they lose their queen.

The loss of the queen is an event which has the most marked influence on their conduct. Although the queen is constantly an object of attention and of strong affection to the whole community, they are not immediately sensible of her absence when she is removed from the hive. The ordinary labours are continued without interruption, and it is not till a whole hour has elapsed, that symptoms of uneasiness are manifested, and it is even then only partially displayed. The inquietude begins in one part of the hive, the workers become restless, abandon the young which they were feeding, run to and fro, and, by striking each other with their antennæ, communicate the alarming intelligence very quickly to their companions. The ferment soon extends to the whole community; the bees rush precipitately out of the hive, and seek for their lost queen in every direction. This state of confusion continues for two or three, and sometimes for five hours, but never longer. Tranquillity is again re-established; they return to their labours; and selecting one of the larvæ that is not more than three days old, they break down two of the contiguous cells, sacrificing the larvæ contained in them, and proceed to build up one royal cell from their ruins. They then supply the worm with the food necessary to promote its quick growth; and, leaving untouched the rhomboidal bottom, they raise around it a cylindrical enclosure. In three days, the larva has grown to such a size as to require an extension of its lodging, and must inhabit a cell nearly of a pyramidal figure, and hanging perpendicularly. A new pyramidal tube is therefore constructed with the wax of the surrounding cells, which is soldered at right angles to the first, and the bees, working downwards, gradually contract its diameter from the base, which is very wide, to the point. In proportion as the worm grows, the bees labour in extending the cell, and bring food, which they place before its mouth, and round its body, forming a kind of coiled zone around it. The worm, which can move only in a spiral direction, turns incessantly to take its food before its head; it insensibly descends, and at length arrives at the orifice of the cell. It then transforms itself into a pupa, is enclosed with a covering of wax, as before described, and, in the space of ten days, the original loss is thus repaired by the birth of a new queen. Schirach found, that if a number of bees be confined with even a single larva, which, in the natural course would have become a working bee, they immediately set about giving it the royal education above related, and thus raise it to the dignity of queen.

While the hive remains without a queen, swarming can never take place, however crowded the hive may be. The young queens are suffered to come out of their cells without impediment, and, after a number of deadly combats, the empire remains with the survivor. Huber has made the singular observation, that two queens, however inveterate may be their mutual hostility, never actually both destroy each other; and that when, in the course of their contest, they are placed in such a relative position as that each has it in her power to strike a mortal blow on the other with its sting, they suddenly separate, and fly from each other with every appearance of being panic-struck. The final cause of the instinct that prompts this conduct is sufficiently obvious, as, without it, the hive would be altogether deprived of a queen.

The bees recognise the individual person of their own queen. If another be palmed upon them, they seize and surround her, so that she is either suffocated, or perishes with hunger; for it is very remarkable that the workers are never seen to attack a queen-bee with their stings. If, however, more than eighteen hours have elapsed before the stranger queen be introduced, she has some chance of escape. The bees do, indeed, at first seize and confine her, but less rigidly; and they soon begin to disperse, and at length leave her to reign over a hive, in which she was at first treated as a prisoner. If twenty-four hours have elapsed, the stranger will be well received from the first, and at once admitted to the sovereignty of the hive. If a supernumerary queen be introduced into the hive, she is laid hold of by the bees, and presented to the reigning queen, while a ring is formed by the bees, who continue to be spectators, and even promoters of the combat, in which one or other of the queens is destined to perish. Schirach and Reims had imagined that, in these circumstances, the stranger met her death from the hands of the working bees, but this mistake has been rectified by Huber, who gives the account above stated.

Retarded Fecundation.

If the impregnation of the queen be delayed beyond the twenty-first day of her life, she begins soon after to lay the eggs of drones, and produces no other kind of eggs during the remainder of her life. This very curious and unexpected fact was discovered by Huber, and has been satisfactorily established by his very numerous and varied experiments, although its explanation is perhaps attended with insuperable difficulties. The body of a queen, whose impregnation has thus been retarded, is shorter than common, the extremities remain slender, while the two first rings of the abdomen, or those next the thorax, are uncommonly swollen. On dissecting the double ovary, both branches were found to be equally expanded and equally sound; but the eggs were apparently not placed so closely together as in common queens. It was not correctly ascertained, whether the queens, whose impregnation was retarded, laid a number of drone eggs corresponding to the whole number of eggs, both of workers and drones, which they ought to have deposited; but it is certain that they laid a greater number of drone eggs than they ought naturally to have done. On these occasions, the instinct of the queen-bee appears to suffer, for she then lays her eggs indiscriminately in large and in small cells; those laid in large cells producing large drones; those in small cells small

drones; and she has been known to lay the eggs of drones even in royal cells, some of which are always constructed when the queen begins to lay male eggs. It is curious that the workers were, on these last occasions, deceived, and treated the embryo drones as if they had been truly of the royal brood.

Prolific Working-Bees.

One of the most remarkable facts concerning the generation of bees, is the existence occasionally of prolific workers, the discovery of which we owe to Reim. Although it was doubted by Bonnet, its reality has been fully confirmed by the researches of Huber; and it explains what was before unaccountable, the production of eggs in hives absolutely destitute of a queen. It is also remarkable, that the eggs thus produced are always those of drones. The origin of these supplementary queens is accounted for, from their having passed the vermicular state in cells contiguous to the royal ones, and from their having, at an early period, devoured some portion of the stimulating jelly, which was destined for the nourishment of the royal brood; and from their ovaria thus receiving a partial developement, which renders them susceptible of being impregnated. It is curious that these imperfect queens are still objects of jealousy and animosity to the queen-bee. How they become impregnated has not been ascertained; but the fact of their being productive was a strong confirmation of the truth of Schirach's theory concerning the sexes of bees. Needham, to whom the fact was known, had eluded the force of the argument, by pretending that these bees did not belong to the working class, but were real queens of an unusually small size. The supposed absence of ovaria in the working-bee was still, indeed, a difficulty which tended to throw some degree of doubt on the correctness of Schirach's doctrine. No person, as Bonnet repeatedly alleges, could suppose that these organs, however minute they might be, had escaped the penetration of Swammerdam, who was unrivalled in his anatomical skill in all that related to insects, and who had bestowed great labour in the examination of the structure of the bee. What had eluded his scalpel and microscope, was reserved for the still finer hand, and more dexterous dissection of a lady. Miss Jurine, the daughter of the celebrated naturalist of Geneva, has discovered, by adopting a particular method of preparing the object to be viewed, the rudiments of ovaria in the common working-bee; she examined a great number, and never failed to find them. Cuvier, in his *Leçons d'Anatomie Comparée*, mentions a suspicion that he had seen some very small oviducts in the working-bees, a suspicion which we now find to be completely verified.

Effects of Mutilations.

We have next to relate the event of experiments of a more cruel kind, but which illustrate several points in the physiology of these insects. The amputation of the four wings of the queen did not interfere with her laying of the eggs, and the workers did not show her the less attention on account of her being thus mutilated. Of course, if the operation be performed before she is impregnated, she remains barren, since it is necessary for the sexual congress that she should fly out of the hive. The amputation of a single antenna appeared to be productive of no bad consequence of any kind; but the removal of both the antennæ was followed with singular effects. The queen who had suffered this operation ran about in apparent disorder, dropping her eggs at random, and was incapable of directing her trunk with precision to the food that was offered her. At times she appeared desirous of escaping from the hive, and when this was prevented, she returned in a state of delirium, was indifferent to the caresses of the workers, and received another similarly mutilated queen, that was presented to her, without the least symptom of dislike. The workers, on the other hand, received the stranger queen with great respect, although the first still remained in the hive. A third queen, not mutilated, was next introduced; she was very ill received, and immediately detained and kept close prisoner. When the queen deprived of her antennæ was allowed to quit the hive, she was followed by none of the workers, and was abandoned to her fate.

Variations in their Mode of Building.

Bees naturally build from above downwards, but may, by a particular artifice, devised by Huber, be induced to reverse this process. For this purpose, a glass hive, with slender laths fixed at the bottom of it, must be provided, and the bees confined in it. They are unable to fasten themselves to the smooth surfaces, and, therefore, establish the foundations of the combs on the wood, and are forced to proceed in a direction opposite to the usual one; in this way Huber was enabled to observe their proceedings. But the readiest mode of inducing them to build in any particular direction, is to supply them with portions of ready-made combs, which should be fixed with wires in the proper position; and they will always continue to complete them upon the model presented to them. The hive which Huber recommends is constructed on this principle, consisting of upright frames of a square form, fitted to each other, and of such a size as just to contain each of them a single comb; by separating these, every part of the hive can be laid open and examined with the utmost ease. Féburier has improved upon this construction by changing the shape of the frames from a square to a trapezium, having an acute angle at the summit, a form which allows the moisture that collects at the top to run down the sides more easily than it would do from a flat roof. In this way, any portion of the honey or wax may be removed at pleasure, without hurting or incommoding any one of the bees; and artificial swarms may, at the proper season, be readily procured, by dividing the hive into two portions, and adapting empty frames to each portion.

Enemies of Bees.

The wasp and the hornet have long been known as the determined enemies of the bee, committing great ravages among these weaker insects; they attack them individually, but oftener commit their aggressions in large armies, on which occasions numbers perish on both sides. In some parts of America, wasps have multiplied to so great a degree, as to render it impossible to rear bees. Among quadrupeds, the ant-eater occasionally devours them. The bear and the badger overturn the hives, and plunder their contents. Rats and mice are very formidable enemies, as they invade them at all seasons, and especially during their torpid state, when they are incapable of revenging the aggression. The woodpecker may succeed in breaking through

the hive, and then speedily destroys all its inhabitants; the swallow, the sparrow, the titmouse, the cuckoo, and the *Merops apiaster*, or bee-eater, and poultry of every kind, prey upon them separately. According to Bosc, they are also food for the shrikes, and for the *Falco apivorus*. Lizards watch for them, and seize them as they alight near the hive. Toads occasionally devour them. They are in some danger from the larger kinds of spiders, and of *Libellulæ*, as also from the *Philanthus apivorus* of Fabricius. But the most insidious and destructive enemy of these insects is the moth; various species of which, particularly the *Phalena mellollena*, insinuate themselves into the hive, and deposit their eggs unperceived between the cells, in such numbers, that the hive is soon overrun with the larvæ, where they are hatched, and the bees are forced to abandon the hive. A new enemy of the same tribe has been lately discovered by Huber, in the *Sphinx atropos*, well known by the name of death's head. Towards the end of autumn, when the bees have filled their magazines, a loud hum is sometimes heard near their habitation, and a multitude of bees come out during the night, and fly about in the utmost confusion. The tumult continues for several hours, and the next morning a number of dead bees are strewed before the hive. On examining the hive, it is found to have been robbed of all its honey, and the bees do not return to it. These effects result from the incursions of the sphinx, which watches its opportunity to introduce itself into the hive during the night, when the bees are deprived of the advantages of vision, which the sphinx enjoys in greater perfection at this period. By rendering the door-way extremely narrow, so as only to admit a single bee at a time, this accident may be prevented; and it is curious that the bees themselves frequently anticipate this danger, and provide against it by employing, of their own accord, the very same mode of defence. They construct a thick wall which barricades the entrance, and resembles a regular fortification, with bastions, casemates, and massive gateways. They often, indeed, have recourse to a similar contrivance for protection against the pillaging-bees, enabling them to repel the assault with greater effect. At other times when the danger is less pressing, the inconveniences of so narrow a gateway being strongly felt, they enlarge it by removing the fortification they had built, and do not again construct it unless the appearance of the enemy in the ensuing season should inspire them with fresh alarms. If, on the other hand, the precaution of narrowing the gateway should already have been taken by the cultivator, the bees, feeling themselves secure, spare themselves the unnecessary labour of erecting these walls. This single trait in their history is a sufficient refutation of those theories which ascribe all their actions to the operation of a blind indiscriminating instinct, and would exclude every species of foresight and reflection. (W.)

BEGGAR.

[Defi]nition. THE word literally means, *one who begs*. In a more restricted sense, it means one who begs the means of subsistence. Even this definition, however, is too extensive for the idea to which, in this article, we mean to confine it. The class, in fact, of the persons to whom the term *beggar*, in the most restricted sense, applies, cannot easily be separated by an exact line of distinction from the kindred tribes. You cannot define the beggar as one who asks the means of subsistence, or money to purchase it, from passengers in the streets and highways; because there are people who beg from house to house. If you include those who beg from house to house, even that will not suffice, because there are persons who beg by letter, and have various means, beside language, of bringing to the knowledge of others the tokens of real or fictitious distress. And, if you make a definition extensive enough to embrace all these classes, you will make it include persons whom no one regards as standing in the rank of beggars; every person, almost, who, from any cause, is brought to require the assistance of others. It is not useless to contemplate how these classes run into one another; because it teaches the necessity of delicate and cautious proceedings, when we take measures of cure; especially if *force* enters at all into their composition.

[Diffe]rent [speci]es of [begg]ars. 1. Of the class of persons to whom, in the common use of language, the term Beggar is with propriety assigned, there is one distinction which is obviously and commonly made; that is, into those who beg from necessity, and those who beg from choice. In each of these divisions, there is great variety. For a description of the field of mendicity we derive helps from the *Report of a Committee of the House of Commons*, appointed in the year 1815, to inquire into the state of mendicity in the metropolis. The inquiry is very imperfect; the interrogation of the witnesses superficial and unskilful; the information which they give not followed up, by exploring other and better sources, which they indicate; but, as people had been left to casual observation, to fancy, and conjecture before, the facts and conjectures which that Report lays before us are still the best information we possess.

Nothing more strongly indicates the deficiency of our knowledge upon this subject, than the different opinions which the Committee received on the proportion between those who beg from necessity, and those who beg from choice. The persons examined were those of whom the Committee made choice, as having possessed peculiar opportunities of knowledge; and this was a point to which their inquiries were peculiarly directed. Yet one part of the witnesses strongly asserted, that a proportion as large as one half were beggars from necessity: another part of them asserted that all beggars, with hardly any exception, prosecuted the occupation from choice.

Mr Martin, the conductor of an inquiry into the state of mendicity in the metropolis, under instructions from his Majesty's Principal Secretary of State for the Home Department, which inquiry extended to about 4500 cases, stated, as "the general result of his information, that beggary is, in very many cases, perhaps in about half the cases of those who beg, the effect rather of real distress, than of any voluntary desire to impose. So far from having found, amongst those who have attended at the office, any reason to think that the whole was a matter of imposition, I have (says he) found cases of the most acute suffering, which have long been concealed, of some of the beggars, who belonged to parishes in the metropolis, who have not made their cases properly known to the parish-officers, and who have ventured to slip out of their parishes, not so much because they wished to impose, as because they were driven by distress to beg." Mr Martin grounded this conclusion also upon the general fact, that the number of women was much greater than that of men, and that of married women greater than that of single. "Men," he remarks, "are stronger than women, have more resources, and are better able to provide for themselves; and single women are more eligible for service than married, and usually have only themselves to maintain."

The Rev. Henry Budd, who had been fourteen years Chaplain to Bridewell Hospital, to which the greater number of the persons taken up for begging in the streets of London are committed, was asked, "Have you ever known a worthy person begging in the streets?"—"Yes; I have known many that I should call worthy; and, I think I could mention some who have come up from the country distressed for want of work. They think London is paved with gold, or presents opportunities the country does not; and they find themselves here without friends. I have met with many whom I considered very worthy."

Of these two witnesses, the personal experience in the case was equal, or probably superior to that of all the rest taken together.

From other witnesses, however, of whom the experience was also great, the committee received affirmations of an opposite import. Mr John Cooper, a visitor of the *Spitalfields Benevolent Society*, was asked, "From the observations you have made upon the state of poor families, do you think any worthy families have recourse to begging in the streets?"—*Ans.* "I have no idea at all, from what has come under my own observations, that, in any individual case, persons, that were worthy objects, however distressed they were, have had recourse to street-begging."

Mr John Doughtry, a gentleman much in the habit of visiting the habitations of the needy, was asked, "In your opinion, do many worthy, honest, industrious persons have recourse to begging, or does this class of society consist chiefly of the idle and profligate?"—*Ans.* "The instances in which worthy, honest, industrious persons have recourse to begging are extremely rare. They will, in general, rather starve than beg. A person of veracity, who sometime ago visited 1500 poor families in the neighbourhood of Spitalfields, affirms, that, out of full 300 cases of *abject poverty and destitution*, and at least 100 of LITERAL WANT AND STARVATION, not a dozen had been found to have recourse to begging. Many of the most wretched of the above cases had been, not long before, able to support themselves in some comfort, but want of employ had completely ruined them. They were, at that moment, pressed by landlord, baker, and tax-gatherer; had pawned and sold every thing that could be turned into money; were absolutely without a morsel of food for themselves or family; but still had not recourse to begging. As a general fact, the decent poor will struggle to the uttermost, and even *perish*, rather than turn beggars."

This is heroism, in comparison with which, that of the Herculeses and the Hectors, ancient and modern, sinks into nothing! What an admirable foundation of virtue must be laid, in these minds, which even thus endure the horrors of death, approaching with all the torments of hunger and cold, rather than seek to relieve themselves by courses reputed disgraceful! And how unworthily is this class of persons traduced, by those who represent them as capable of being restrained by nothing but a dungeon or a bayonet; and who, by their ignorance of human nature, so cruelly prolong the needless miseries under which it labours!

According to the experiment mentioned by Mr Doughtry, and it is upon a large scale, and a part of the population (the circumstances of the people in Spitalfields are not favourable to virtue) which may be reckoned below rather than above the common standard, out of 400 individuals, of the lowest order, 388 will consent to perish by hunger, rather than beg. In confirmation of this testimony, an extraordinary fact has come to our knowledge. We have been informed by a gentleman, whose knowledge of the circumstances and behaviour of the journeymen in the metropolis may be regarded as in a very unusual, or rather an unexampled degree, minute and correct, that, of this important portion of the labouring population, no one ever begs; that such a thing as a journeyman tradesman, or any of his family, begging, is almost unknown; and may, with certainty, be pronounced as one of the rarest of contingent events. When it is considered to what an extraordinary degree most of the employments by which these men earn the means of subsistence are liable to fluctuation; that thousands of them are for months together deprived of work, as was the case with thousands, for example, of the carpenters and bricklayers during the severe winter of 1815; that of those the whole must be reduced to the most cruel privations, and a great proportion actually starve unpitied, unheard of, and unknown; the resolution by which they abstain from begging, should be regarded as one of the most remarkable phenomena in the history of the human mind.

It may still be possible to reconcile these undoubted facts with the testimonies of Mr Martin and Mr Budd. It appears that a great proportion of the beggars to whom they allude are women, and women with families; whose spirits, where they are left to themselves, are less able to support them, and to make

Beggar.

the dread of disgrace an overmatch for the pains of hunger and the terrors of death. It appears, also, that a large proportion of them are the wives of soldiers, in the company of whom the sense of disgrace is apt to lose its pungency. People from the country, simple, and without resources, add a portion to the number of those whose mendicity cannot be regarded as the effect of vice. And it cannot, surely, be a source of wonder, that, out of so large a population, so great a portion of whom are liable to the extremity of want, there should be a few with whom the dread of disgrace should not be so powerful a motive as the love of food, and of life.

Number of Beggars.

2. Of the number of beggars in the metropolis (and no attempt has been made to discover it in the rest of the country), the labours of the Committee have ascertained hardly any thing. At the time of the first inquiry, which was made by Mr Martin, 2000 cases presented themselves. This, by a vague estimate, he supposed might be about one-third of the whole; and allowing at the rate of a child and a half to each principal, he conjectured that the whole number might be about 15,000. If this be supposed a tolerable approximation, with regard to the metropolis, a comparison of the population of the metropolis with that of the whole country, will give an approximation to the number of beggars in the kingdom.

3. With regard to the number of beggars, an important fact appears to be ascertained; that it is gradually diminishing. Mr Martin said, "I do think that the number of beggars has something decreased since the first inquiry, nine years ago; and I am very much confirmed in that opinion, by what persons have told me, that they have not seen so many as they did. I really think there are not so many by one-fourth." Sir N. Conant, of the Police-office in Bow-street, said, "I think the number of beggars was greater thirty years ago than now. I have acted as a magistrate for more than thirty years. —Do you mean greater in proportion to the population?—Greater in fact. I am sure, on my own recollection and observation, that mendicity is a less nuisance now than it was thirty years ago."

Sir Daniel Williams, a magistrate attending the Police-office in Whitechapel, was asked, respecting the beggars in that district, "Do you think the number has increased within any given period?"—*Ans.* "I think, within the last two years, they have rather diminished." Mr John Stafford, chief clerk of the office in Bow-street, said, "It strikes me, from the knowledge I have had, having been chief clerk of the Police-office in Bow-street ever since the year 1803, that there are not the same number of beggars about the streets that there used to be; I think the number is considerably decreased." This corresponds so fully with what strongly meets the observation of every attentive man, and has been amply given in evidence before the Committees of the House of Commons, on the state of education, and the police of the metropolis, during the last session of Parliament, respecting the great improvement in the morals and in the manners of the lower orders, that it may be regarded as a fact of which no reasonable doubt can be entertained.

Deceptions practised by Beggars.

4. This is the little which appears to be known with regard to the proportion between the beggars from choice, and the beggars from necessity, and with regard to the number of the whole. We shall next speak of the arts by which it is understood that the trade of beggars is carried on. This appears to be the grand subject of curiosity. There is a mystery about this, and a fancied ingenuity, which those who wish for the marvellous are very much stimulated to explore and to magnify. The fact, however, is, that the contrivances, upon the whole, are few, and almost all of them obvious, and coarse. They are expedients for exhibiting as much as possible of the appearances of distress. Of these, rags and nastiness are one portion, which it surely requires but little ingenuity to display. The different kinds of bodily infirmity, chiefly those which incapacitate for labour, are the remaining portion. On this subject the most authentic details which have been collected, are those contained in the *Report of the Committee on Mendicity*. We shall select from the evidence, as far as it goes, the description of the principal arts; and the intelligent reader will perceive, that, with regard to invention, they are near the bottom of the scale.

The Reverend William Gurney said, "I am rector of St Clement Danes, and minister of the Free Chapel in West Street, St Giles's. In the course of my ministry there, I have had a great deal of occasion to visit persons in very great distress. I have ascertained, that there are four different ways of begging. Some are by letters, which are sent by post; and some are what we call knocker beggars, who go from house to house, knocking at every door. If they get a knowledge of any respectable person in the street, they pretend they have received money at his house, to make a sum to pay rent, or the postage of a letter from a son who has been six or seven years at sea, and from whom they expect a remittance; or for other purposes. On these occasions they have generally some written statement in their hands. Some beggars are stationary. They come to their stand at a certain hour, where they remain all day, or after so many hours repair to another. Of these beggars, those who are blind, or maimed, or have children, succeed the best. There are others, women and children, who are moveable beggars, following not the street but the people. For instance, at the time of the play, they are always very near the theatres; and if they see a young gentleman and a young lady walking together in deep conversation, they will pester them, and run before them till they give them something to get rid of them. Those people, at other times of the day, if it is a Sunday, for instance, will be found near chapels where there are large congregations; they know as well where the large congregations are as possible. There are others who are continually begging from house to house; they go through a great number of streets in the day, occasionally taking a ballad, or a bunch of matches, and pretend to be picking up bones in the street, and early in the morning kneeling down to areas, tormenting the

cook when she is busy in the kitchen, until they get some broken victuals, as they call it, but they actually sell this victuals; that I have found out. In St Giles's there are some eating houses for the very poorest mendicants, where they go and sell this victuals they get from different houses."

This is a correct description of the most common cases of begging. There is one case, by no means uncommon, which we do not perceive described by any of the witnesses; that, when three or four men, being or appearing to be lame or maimed, and most commonly in the guise of sailors, go out in a body, singing with great loudness, and almost barricading with their bodies the streets through which they move, in such a manner, that nobody can pass without a vehement onset, while the timid or sensitive hardly dare to resist. Of course, this takes place only in these streets in which there is least danger of their being taken up.

The following is a description given by the Reverend W. Gurney, of some other classes of beggars. He had mentioned a set of applications frequently made to him, by persons who pretended that prize-money, or benefits of some other sort were due to them, of which, however, being deprived by want of knowing the steps to be taken, they entreated a letter to somebody who would instruct them; "but their object was to get a letter with my name to it, with which probably in a short time they could get L. 20. If I have written to any body in the office of the Treasurer of the Navy, whom I knew, for instruction or counsel how they ought to act, recommending the bearer to this person for any information he could give upon such points; if I only said, I beg leave to recommend the bearer to your notice, they would paste this upon another sheet of paper, cutting off the bottom part (and one person was detected in doing this), and then they would take the name at the bottom, and so paste it together, making a kind of a recommendation of this person: knowing who I was acquainted with, some other clergyman, perhaps setting me down as giving them 10s.; that clergyman is induced to give them 10s. also, and to send them to some benevolent person in his congregation: and so they go on till they have got L. 20: and that has frequently been done, I do not mean always by imposition. But, in many cases, where persons have been in distress, through providential circumstances, I have written to another clergyman, saying, such a woman was distressed, and had so many children, and that her husband was out of work, and that this I knew to be the fact, for I had inquired. I have given half a guinea, and have given the names of others; and by this means sufficient relief has been procured without coming to the parish at all. But the impositions on the subject of recommendations are very great; I have had letters from all parts of the country, inquiring whether I gave a general recommendation to such a person; and they have said, we saw a letter purporting to be in your handwriting; we were pretty confident it was not written by you, but it was a very good imitation. One man in Staffordshire, where I had lately been, got a great deal of money upon such a letter. I conceive the beggars in the streets are more numerous at one time of the year than another; and it would be supposed the time of the year when they were most numerous, would be in the early part of the winter; but that is not the case, for now they are as thick as at any time of the year. I have been endeavouring for a long time to ascertain the reason of this; and the first obvious reason for the influx of beggars into the metropolis, at this season of the year, is, with respect to one class of beggars, those who do it by letters or recommendations, and not going from house to house, that they take advantage while Parliament is still sitting, or particular persons being in town; they perhaps are pretty stationary in London all the year; but they are more anxious at this time, and therefore more heard of, because people are going out of town, and therefore they are taking time by the forelock, and work double tides; that is the reason I very frequently have letters sent by friends of mine in affluence, Mr Wilberforce and others, requesting me to inquire into particular cases, and if I found them to be as represented, to give them so and so. I have generally been troubled more at this season of the year than at any other. As to those who knock at the door to beg, the reason of their being so numerous at this time of the year, I apprehend, is, that many come out of the country with a view to take the early hay-time about the metropolis, but they bring always a large suit with them. If a man comes to mow in the neighbourhood of the metropolis, they mow their way back again, the harvest beginning sooner near the metropolis; they bring with them a wife and six or seven children. I have seen hundreds coming up through Stanmore, when I resided there. They generally come too soon, and the streets are filled with these poor people: One says, if I could but get money to buy a fork I could get work; and another, if I could get money to buy a rake, I could get employment. I have had half a dozen with me since Saturday, stating that they came up to get a job of work, but the market is overstocked: there are so many Irish here. The consequence of these people coming is, their children are immediately set to begging in the streets, and with the dust upon them, having travelled a great way, and frequently in real want, they move the compassion of people very much; they are frequently sitting with papers stuck in their hats. In the course of six or eight weeks great numbers of those will disappear; the husbands will get to mowing, their wives will get a hay-fork, and the children will get to weeding in the gardens: Then they get a dreadful habit, by coming to the metropolis, a habit of idleness and drinking; and those children are annually instructed in idleness and drinking, and of course lying; idleness is sure to bring on lying and theft. I dare say there are very few of these mendicant children who are not trained up to pilfer as well as to beg; they come principally, I believe, from the manufacturing counties. On a journey from Birmingham to London, two years ago, I passed not less than two hundred with their wives and children, who were begging as I passed."

The following statement is inserted in the Re-

port of the Committee, under the title of "Information communicated by three members of a Society instituted for Benevolent Purposes:"

"In Nicholas-court, Rosemary-lane, there are about twenty beggars, male and female, of the very worst description, great impostors, drunkards, blasphemers, &c.: their rendezvous the City of Carlisle, Rosemary-lane.

"In Mill-yard, Church-lane, about ten female beggars.

"In White Horse-court and Blue Anchor-yard, about fourteen beggars.

"In Dotridge-street, New-street, and St Catherine's-lane, about thirty female beggars.

"In Angel-Gardens and Blue Gate Fields, about twelve beggars, four of them blacks.

"In Chapel-street, Commercial-road, six beggars.

"In Goodman's-yard, Minories, six beggars affecting blindness.

"In the neighbourhood of Shoreditch and Bethnal Green, about thirty-five families may be computed at one hundred and fifty members, who subsist by begging and plunder. There are about thirty Greenwich Pensioners, who hire instruments of music and go out in parties.

"If each beggar does not procure at least 6s. *per* day, they are considered very bad at their business.

"In visiting George-yard, leading from High-street, Whitechapel, into Wentworth-street, we found there were from thirty to forty houses apparently full of people; and being desirous of knowing the situation they were in, we gained access to several of them where we had formerly visited distressing cases; and from the information we collected, we conceive that in these houses there are no less than two thousand people; the whole place, indeed, presents such a scene of human misery and dissipation as can hardly be conceived. We learned from those we had access to, that one half of these inhabitants subsist almost entirely by prostitution and beggary; the other half are chiefly Irish labouring people.

"In Wentworth-street (adjoining the above yard) there are a great many houses occupied by inhabitants similar to those in George-yard. One of these (a private house, No. 53) we visited, and were not a little surprised to find that it contained one hundred beds, which are let by the night or otherwise, to beggars, and loose characters of all descriptions. In some of the lanes leading from this street, there are other houses of the same kind."

Mr Sampson Stevenson, who had been Overseer of the parish of St Giles's the preceding year, and by that circumstance forced into an acquaintance with the practices of its begging inhabitants, said,—"There is a man whose real name I do not know, but he goes by the name of Granne Manoo. He is a man who, I believe, is scarcely out of jail three months in the year; for he is so abusive and vile a character, he is very frequently in jail for his abuse and mendicity. He is young enough to have gone to sea, but I believe he has been ruptured, consequently they will not take him. I have seen him scratch his legs about the ancles, to make them bleed; and he never goes out with shoes. That is the man that collects the greatest quantity of shoes and other habiliments; for he goes literally so naked, that it is almost disgusting for any person to see him in that situation. Another man I have known upon the town these fifteen or twenty years; he is a young man as nimble as any man can be. I have seen him fencing with the other people, and jumping about as you would see a man that was practised in the pugilistic art. He goes generally without a hat, with a waistcoat with his arms thrust through, and his arms bare, with a canvass bag at his back; he begins generally by singing some sort of a song, for he has the voice of a decent ballad-singer. He takes primroses or something in his hand, and generally goes limping or crawling in such a way, that any person would suppose he could not step one foot before another. I have also seen him, if a Bow-street officer or beadle came in sight, walk off the ground as quickly as most people. There is a man who has had a very genteel education, and has been in the medical line, an Irishman; that man writes a most beautiful hand, and he principally gets his livelihood by writing petitions for those kind of people, of various descriptions; whether truth or falsehood I know not, but I have seen him writing them, for which he gets from sixpence to a shilling.

"Do you know whether they change their beats?—I have seen them come out from twenty to thirty out of the bottom of a street, formerly called Dyot Street, now called George Street. They branch off, five or six together, one one way, another another. Invariably, before they get to any great distance, they go into a liquor-shop, and if one amongst them has saved (and it is rare but one of them saves some of the wreck of his fortune over night), he sets them off with a pint of gin, or half a pint of gin amongst them, before they set out. Then they trust to the day for raising the contributions necessary for their subsistence in the evening. They have all their divisions. The town is quartered into sections and divisions, and they go one part one way, another part another. In regard to the mendicity of people begging with children, I can give a little information upon that. There is one person, of an acute nature, who is practised in the art of begging, will collect three, four, or five children from different parents of the lower class of people, and will give those parents 6d. or even more *per* day, for those children to go begging with. They go in those kind of gangs, and make a very great noise, setting the children sometimes crying in order to extort charity from the people. I had an opportunity of seeing a number of those cases, being a parish officer. They will sometimes have the audacity to come to the Board for relief, which we have four days a-week: there is a great deal of money given in St Giles's. They will, if necessary, swear they are all their own children, and being, in general, of Irish parents (where-ever the tree falls it must lie), consequently they get some relief till we can make proper inquiry; but, in a very short time, they are found out, for we generally send to the place they come from; but the landlords and landladies are so cunning, they would swear that the whole of those children belonged to them. But we have people of their own class, to whom we

are obliged to give something to detect the impositions we are liable to, for we are often imposed upon. A great many of those cases were before me last year as a parish officer; where a woman had been in the habit of receiving 5s. a-week, and at last a woman of her own country came forward, and taxed her that three of the children were not her own. We never saw them again, but they went into other parishes, such as Mary-le-bone, St Andrew's, and other parishes, and sought relief there; they know we cannot remove them. We have had other persons whose families are their own, and when they have a habit of begging, and get a good deal of money by that trade, they will not go to work. But we have complaints from a variety of persons round Bedford and Bloomsbury Square, of those persons being nuisances. And when the parties have come to the Board, we have offered them the house to come in with wife and children:—" No; I expect my husband home very soon, and I will not come into the house." In those cases we get rid of them, but we invariably offer them the house. When they will not take it, then we stop the relief, for I think the house is the best thing for a family of children, and a distressed family of that description."

Mr William Dorrel, inspector of the pavement of St Giles's and St George, Bloomsbury, said,—" One evening I was coming down Tottenham-court Road; a man and a woman, both beggars, were quarrelling. The man swore at the woman very much, and told her to go down to such a place, and he would follow her. I said to myself, I will see this out. She appeared to be pregnant, and very near her time. I went down to Sheen's, I think he sent her there. There was a quarrel, and he said, " I will do for you presently;" and he up with his foot and kicked her, and down came a pillow stuffed with straw, or something of that kind; she was very soon delivered. I have been informed of a circumstance respecting a man of the name of Butler, that went about; he had lost one of his eyes. I am told he had been to sea. He had a dog, and walked with a stick; the dog went before him; he hit the curb-stone. People supposed he was blind of both eyes; he turned his eye up in such a way that he appeared blind. When he returned to his hotel, he could see as well as I could, and he wrote letters for his brother-beggars. This man has been dead two or three months."

The following is a curious fact, testified by Mr T. A. Finnigan, master of the Catholic Free School in St Giles's.—" About two years ago, there was an old woman who kept a night-school, not for the purpose of instructing children to spell and read, but for the sole purpose of teaching them the street language, that is, to scold; this was for females particularly. One female child, according to the woman's declaration to me, would act the part of Mother Barlow, and the other Mother Cummins; these were the fictitious names they gave. The old woman instructed the children in all the manœuvres of scolding and clapping their hands at each other, and making use of the sort of infamous expressions they use. This led them into the most disgraceful scenes. When these children met, if one entered into the department of the other the next day, they were prepared to defend their station, and to excite a mob."

This is nearly the whole of the information which is contained in this celebrated Report, with regard to the *arts* which are employed by the beggars of the metropolis. We shall next consider the estimate which ought to be formed of their *gettings*. On this subject also exists a great bias to exaggeration. Both the Committee, and these witnesses, with certain exceptions, appear to have been led by it.

Probable Amount of the Gains of Beggars.

Mr Gurney had heard of one individual who boasted that he could with ease earn 5s. a-day; that he would go through sixty streets, and that it was a poor street that would not bring him a penny. Sir Nathaniel Conant, however, being asked, " Did it ever come to your knowledge, what any of the mendicants got?" made answer,—" I have heard very large sums stated, but I disbelieve many of them; I have not known of money being found about them; there are a good many very impudent fellows certainly about the streets, who are very troublesome: those who have been taken up have been seldom found with more than a shilling or two, but I believe some of them had hoarded at home. There was a woman brought before me, when I acted at Marlborough-street, who had a caddy in which there were nine or ten guineas hoarded."

Joseph Butterworth, Esq. a member of the Committee, stated as an inference from credible information which he had received respecting their mode of spending, that their daily acquisitions would not be less than from 3s. to 5s. each. One particular girl, however, whom he examined, stated that 1s. 6d. was the common amount of what she was able to collect, though on some days she made as much as 4s. or 5s.

Mr Sampson Stevenson was asked,—" Has it fallen within your knowledge what the largest sums are that have been gained by beggars in the course of the day?—That I have been unable to ascertain, but I have heard them brag of 6s., 7s., or 8s. a-day, or more, according to their luck, as they call it; and if one gets more than the others, they divide it with the rest."

It appears from the words themselves of the evidence on this point, that it is insufficient to prove anything. It is either the result of hearsay, which hearsay was probably the result of conjecture, not of knowledge; or it is founded on what the beggars themselves have said, when in a boasting humour; that is, when actuated with a desire to make their gettings appear as large as possible, and when, of course, their own declarations about the amount of them are, as evidence, of little or no value.

6. The ground on which the opinion of the great profits of begging seems chiefly to be founded, is the notion which is entertained of their expensive mode of living. It is therefore necessary, before we adduce the remarks which appear to be called for on the subject of profits, to state the evidence which has been furnished on the subject of expence.

The Reverend William Gurney was asked,—" Have you understood that the beggars' walks are considered as a sort of property?—Yes; I have

no doubt of it; they never interfere one with another.

"And that a blind man stationed at a particular place, drives away others who interfere?—Yes; and they have their rules and their carousings: There is a house in Kent Street, where I have seen a great fat man, who moves himself about on a wooden board. When I lived near the Kent road, I have seen eight or ten of these persons go into a miserable house in the lower part of Kent Street. I have seen tables set; one a very long table covered with a coarse cloth, but a clean one; and there was something roasting: I was afraid to go in, on account of this man, who was a very violent one; this man was among the rest; they were going to have their dinner at the fashionable hour of seven. There was a cripple among them, who used to be at St George's Chapel in St George's Fields; he used to lie there, and pretend to hold out a pamphlet; he was weak about the loins, and his legs folded under him. I really believe the stories which have been told are not exaggerated.

"Have you any opportunity of knowing that the bread they eat is always of the best?—Yes; they would never eat any but the best wheaten bread."

This evidence proves but little. It is solely by conjecture, Mr Gurney here infers that there was any considerable expence.

Sir Daniel Williams was asked,—"Do you know their mode of life?—There was, in a situation called Church Lane, Whitechapel, some years ago a house of resort of beggars, which was well known to all that class of people in every part of the metropolis, by the name of The Beggar's Opera: the sign of the public-house was the Weaver's Arms, but its slang name was The Beggar's Opera: At the period I am mentioning, these beggars used to resort there of an evening, after having perambulated their different circuits, and lived well; they spent a considerable portion of money, would have hot suppers dressed, and regale themselves with beer, punch, and often other liquor still more expensive."

How unfortunate, and at the same time how strange it is, that not a single question was put to this gentleman, to ascertain whether he knew this by hearsay, or by observation. We are constrained to conclude that it was only by hearsay; because, had he seen the facts, it would have been natural to say so; and because we are never entitled to make an inference stronger than the premises on which it depends.

Mr Butterworth describes scenes of a similar sort, but has attention enough to accuracy to say, that he is only credibly informed of the things which he states. Not a question is put to him about the sources whence his information is derived; much less are any of the persons who gave it brought before the Committee, who ought not to have been contented with the hearsay, when they might have had the original evidence. Mr Butterworth did, indeed, volunteer (for he was not provoked to it by any interrogation) the description of one person. "I know," he said, "a sober hackney-coachman, upon whose veracity I can depend, who has frequently conveyed beggars to their lodgings; and formerly, when he plied in St Giles's, has been called to the public houses which they haunt, to take them from thence, being so intoxicated they could not walk home." If this information of the hackney-coachman was of any value, how wrong it was not to call the hackney-coachman, and get his own information from himself? According to what appears from Mr Butterworth's words, he might have conveyed a beggar from those houses, either twice or two hundred times in his life.

This is a very imperfect mode of collecting evidence.

The only person who gives anything that resembles the evidence of his own observation upon the subject is Mr Sampson Stevenson. He was asked,—"Have you had an opportunity of making observations on the character of street beggars?—A great deal; not only before I was officer, but having been led by being officer to look into the matter, I have made great observations, because there was a house which those kind of people used, not above eight yards from my own house; complaint being made, the nuisance was done away."

"Have you had an opportunity of making particular inquiry into the character of individual beggars?—I have; in fact, I made inquiry, not only of the landlord, but of some of those who seemed to be of a superior class, or petition writers; that was before I was overseer. A year or two ago this house lost its licence; it not only encouraged those kind of people, but people guilty of felonies, and so on. This threw them into other quarters; and they made their residence at a public-house called The Fountain, in King-street, Seven Dials, where they assembled not only at night, but in a morning before they started upon their daily occupations, as they express it; I have seen them come in. As it is a house, the landlord of which is very respectable, and has a family, I have gone into the bar on purpose to see their manner of going on; that is very near the taproom: They come at night, perhaps individuals, and likewise those sailors, or pretended sailors, in a body; but those who go one and two together come also: those who are sailors never take anything on their backs like knapsacks, for they only beg or extort money; but the others beg clothing, or anything they can get, and they always have a knapsack to put it in; they will come loaded with shoes and various habiliments, which, being near Monmouth-street, the place where they translate old shoes into new ones, they sell, and likewise the clothing. I have heard them say, that they have made 3s. or 4s. a-day in begging shoes, for sometimes they got shoes that really were very good ones; and their mode of exciting charity for shoes is, invariably, to go barefooted, and scarify their feet and heels with something or another to cause the blood as it were to flow. I have seen them in that situation many times; and thus they sally out to their different departments, but invariably changing their routes each day, for one is scarcely ever seen in the same direction two days together, but another takes his situation. I have seen them myself; I never saw them outside: but I have seen considerable sums of money pulled out and shared amongst them,

both collectively and those who go two or three together. Victuals I do not think I ever saw brought into that place, for I rather think they throw it away when they get it. Mostly shoes and clothing, and such things as those, which they sell immediately. They stop as long as the house they use is open, and get violently drunk, and quarrel with one another, and very frequently fight; after that they are not allowed to remain, if they were, the licence would be stopped; and very likely there are houses in St Giles's where they spend the other part, if they have any left.

"What is their general character?—They are people that are initiated in this mode of begging; one teaches another their modes of extorting, for I can call it nothing else but extorting: And they are of the worst of characters, characters whose blasphemy it is almost impossible to repeat; they will follow you in a street for a length of space, and if they do not receive money, they give a great torrent of abuse, even all the time you may hear them. Most of them have no lodgings. There are houses where there are forty or fifty of them, like a jail, the porter stands at the door and takes the money; for 3d. they have clean straw, or something like it; for those who pay 4d. there is something more decent; for 6d. they have a bed; they are all locked in for the night, lest they should take the property. In the morning there is a general muster below. I have asked country paupers who have come for relief, how they have been entertained, they say, Very badly: they have gone there. The servants go and examine all the places, to see that all is free from felony; and then they are let out into the street, just as you would open the door of a jail, and let out forty or fifty of them together, and at night they come again; they have no settled habitations, but those places to which they resort; but there are numbers of those houses in St Giles's."

Most of the statements in this declaration are very loose and vague. Yet not a question is put by the Committee to ascertain how far the witness had actually seen and heard, and how far he merely conjectured. No; he is allowed to make up a compound of what he saw, and what he conjectured, just as he pleased, and to leave the ingredients without any distinction. In several things he is palpably and grossly erroneous. For example, he supposes that beggars in general throw away the victuals which they collect. It is likely that they should take the trouble of collecting any thing merely to throw it away! It is likely they should throw away that for which they might get money! Besides, the assertion is contrary to what is actually delivered in evidence to the Committee; the fact, that there are places in St Giles's where the commodity is regularly bought, and where those who have collected it go to sell it.

Nothing is more common, in cases of this sort, than to receive a violent impression from the strong cases, however few; to overlook and forget the small cases, however numerous; and from the strong cases solely to draw every inference to the whole. There are strong marks of this imperfection in the evidence which is given in this Report. Mr Stevenson, for example, in the passage which has just been quoted, gives it, without any restriction whatsoever, as a general characteristic of the beggars of whom he speaks, to be very abusive when their applications are refused. Now, this may safely be pronounced as one of the rarest occurrences. The writer of this article may give his own evidence. He has lived above fifteen years in the metropolis: he has walked more than most people, both in the streets of London, and in the roads and fields immediately surrounding it: he never gives anything to a casual beggar: he has been accosted by thousands of beggars: he cannot at this moment recollect that, in the whole course of that experience, he ever met with one abusive word: but he has a hundred times received a "Thank you, Sir," with a bow or a curtsey from the little boys and girls whom he has refused and repulsed, and to whom it is evident that such a lesson is taught by those on whom their conduct depends. The impostrous beggar, in fact, knows his art too well to lose his temper; and the spirit of the age, so much improved, renders a mild deportment necessary to the success even of the worst employment.

Of this evidence about the great gains of beggars, some parts are directly and strongly opposed to the rest.

Thus we are told that they eat and drink most voluptuously; we are also told that their sleeping places are wretched beyond description. But why should this be, if they were able to afford, in this respect, a higher degree of comfort? Notwithstanding what we are told about their delicate feeding, we are also told that there are eating-houses to which the beggars resort, and in which they buy the scraps of victuals, collected at doors, which the beggars who have collected beyond their own consumption there dispose of. This is no proof that they are generally able to cultivate delicacy.

So slight an exercise of reflection is sufficient to show that the gain of beggars must of necessity be wretched, that one is astonished at the proof which is exhibited of the inattention of mankind, by the number of persons who believe the contrary. According to the principle of population, which supposes a greater number of hands than can find employment, the ordinary occupations and trades may all be regarded as overstocked. The lowest is necessarily the most overstocked of all; because the hands which overflow from the rest are all driven downwards, and the lowest receives the overplus of the whole. The lowest species of occupation is, therefore, of necessity underpaid; that is to say, the wages of the labourer are not sufficient to maintain him with such a family as is necessary to keep the number of labourers, in that occupation, at its existing amount. But it must necessarily be, that the gains of beggars, upon the whole, that is, the gains of an average beggar, are below, and considerably below, the earnings of individuals in the lowest and worst paid species of labour. If it were not, it would follow, that the wretched starving people, employed in the lowest, naturally the hardest and most pain-

ful, species of labour, of consent, will choose to receive a small sum with hard and painful labour, when they might receive a larger sum without any labour at all; it would follow that, out of a multitude, amounting to the greater part of the population, all, or all but an insignificant portion, are endowed with this degree of heroic virtue. This would be to suppose a sensibility to moral considerations which, in the circumstances of an oppressive and degrading poverty, is utterly incompatible with the laws of human nature.

We regard it, therefore, as a matter of demonstration, that the earnings of beggars, as a class, are considerably below the earnings of the worst paid class of labourers.

With this conclusion, however, it is very compatible to suppose, that individuals in the class of beggars, those who have more skill and industry than the rest, may attain to considerable gains; as it is evidently an occupation in which a greater or less degree of skill in working upon the attention and sympathy of mankind must make a considerable difference. The greater you suppose the gains of these skilled individuals to be, the smaller, of course, must you suppose the number of those who make them.

7. We have now exhibited what appears to be the result of all the evidence yet before the public, respecting the actual state of mendicity. The information is exceedingly imperfect, while it is certainly not very creditable to the legislation of our country to be thus ignorant upon such a subject.

It remains for us to present what the existing state of information enables us to discover with regard to the *causes* which operate in this, our own country, to the production of mendicity; in the next place, to explain the *effects* which it is of the nature of mendicity to produce; and, in the last place, to give a list of the operations which appear likely to be the most powerful in effecting a *remedy*,—the object and end of the inquiry.

Causes of Mendicity.

8. With respect to the causes of British mendicity, it will be useful, in the first place, to give what dropped in detail from the witnesses before the Committee.

The cause of which they first begin to speak, is what we may call, in one word, *soldiering*, or the unfavourable change produced in the minds and in the circumstances, both of individuals and of families, when the individuals, or those on whom they depend, become soldiers. There is nothing to which the minds of the witnesses appear to be carried more frequently than to this.

Edward Quin, Esq. a member of the establishment for sending the poor Irish to their own country, speaking of the persons whom they send, declares: " Most of those parties have been, I should imagine nine out of twelve, either in the army or navy, and mostly with families, who have no means whatever of returning home, except, perhaps, a temporary pass, twopence a mile, or a penny a mile; we have known a man, with a wife and six children, coming from the Peninsula, sometimes with 9d. or 1s. or 2s. a-day."

He makes a curious declaration with regard to the Irish, who are already begging in England. The establishment thinks it is better to have *them* in England, as " to send them to Ireland, where there is no provision for them, would be doing them no good."

Mr Colquhoun, the celebrated magistrate, and our grand instructor on the subject of police, being asked for his opinion of the causes of mendicity, said,—" It does appear that there are various classes of mendicants, which are all pretty numerous: First, those that are beggars by profession, who are the immediate objects of the attention of the police. Secondly, those that, from temporary pressure in the winter season, and other seasons when work is slack, or they have any special pressure upon them, fall into want, such as *the wives and families of soldiers*, when their husbands are abroad; or when, from sickness, the head of the family is out of work, many of them have no resource but to ask alms in the streets; that class is forced to do so from the inadequate allowance the parishes can make them, partly arising from their not being parishioners, and arising also from the circumstance of the small sum the parishes can afford to allow, which seldom exceeds the weekly sum required for a miserable lodging. The next class, I am sorry to say, are persons, and *they are pretty numerous, who have allowances from Greenwich Hospital, or who are Chelsea pensioners;* they carry on the trade of begging to a pretty considerable extent. Strangers wander up to town, of which there are a great number, in search of work, with their families, and are disappointed, in consequence of the scarcity of labour, from the supply being greater than the demand; which has been evident to me, and very much so, from attending the very unpleasant duty of appeals against parish rates, and that discloses very often a great number of people out of employ: a number of those who have been wandering up, as well as those stationary in town, do obtain some subsistence, I apprehend, from begging. Those are all the different classes which occur to me at present."

Mr Davis, the agent by whom all persons taken up as beggars and vagrants in London and Middlesex, and passed to other counties, are conveyed, speaking of the difficulty of keeping them from running away, says,—" But the girls that come up with the soldiers are the worst we have; down at Woolwich or at Greenwich, sometimes I have a whole coach-load brought up at a time, some going one way, some another; if it is possible to get away, they will. Some of them say, We must go out of your district, but we will not promise to go all the way home."

The *Edinburgh Society*, also, for the suppression of beggars, say, in their first Report,

" The widows, where not charity work-house cases, were generally found burdened with families, frequently the widows of soldiers killed in battle. The married women were either old, or with families, their husbands being labourers out of employment, or soldiers abroad, many of whom had once enjoyed the county allowance as militiamen's wives, but who had been deprived of that resource in consequence of their husbands having volunteered into regiments of the line. There seems some reason to apprehend that the allowance to the wives and families of militiamen is gradually eradicating that pride which, with the lower ranks in this country, made parish

support disgraceful, and the resource only of the utterly helpless and friendless."

We shall not lengthen this article by pointing out, because they are obvious to all, the circumstances attached to soldiering, by which it necessarily becomes a great source of beggary. These instances are sufficient to prove the impression which has been made by the facts upon the minds of those who have been situated most favourably for observing them.

The next circumstance which is stated by the witnesses before the Committee as a cause of multiplying beggars, is the *state lottery*. It is adduced by more of the witnesses than one, but we must remain satisfied with a specimen. Mr Wakefield was asked, "You have mentioned the lottery, as the second cause; have you any facts to state, justifying that opinion?—I beg to state a very strong instance of an apparently industrious man, who applied to the committee of the *Spitalfields Soup Society* for relief; he was told, that his appearance did not indicate want; and his mode of living was asked. He said he was a "Translator;" which is a business of buying old shoes and boots, and translating them into wearable ones. Inquiry was then made, if he had such a business, why he should then apply for relief; and he answered, as a matter of course, that the lottery was drawing, or about to draw. "Why, how can that affect your business?"—"I have no sale for boots or shoes during the time that the lottery draws." Inquiry was then made as to the truth of the statement, and it was found to be the case, and that he was an industrious and respectable man; and that it was only on account of the loss of his trade that he was brought into that distress.

"How long ago was that?—Two or three years ago; the money went, of course, either in the purchase of tickets, or the payment of insurances in the lottery."

Almost all the witnesses who deliver any opinion upon the causes of mendicity, mention the use of intoxicating liquors as one of the greatest. It is needless, we conceive, to adduce the testimony of any individual in this case. The only mistake, of which there is any danger, in respect to this cause, is the ascribing to it more effects than it produces. Though mischievous, in proportion to the quantity, by every drop that is consumed, it will account for but a small portion of the mischief which we behold.

Local demands for temporary labour often affect the poor very unfavourably. A passage already quoted from the evidence of Mr Gurney, shows in what manner a great number of persons crowding to the vicinity of London in the hay season, are driven or seduced into habits of beggary.

One cause of beggary may here be mentioned, which has not attracted all the attention which it deserves. That is, the mode in which we allow certain classes of the people to pay themselves by a sort of begging. In these unhappy circumstances we allow post-boys, stage-coachmen, and various other classes to be placed. One sort of begging is nearly allied to another. Of the same tendency is the practice by which servants take, and by their well known expectations beg, gratuities from their master's guests. All these are degrading practices, which bring down the mind to the mendicant level. We have no doubt whatsoever, that, of this sort of people, a greater proportion than of others, recruit the ranks of mendicity.

Almost all the witnesses represent the want of education, as standing high in the list of the causes of mendicity. Some of them who had used the greatest range of observation, spoke of this cause with extraordinary emphasis; and of the powerful effects of schooling, as giving that sense of honour to the people, which makes them willing rather to die than to beg. We shall not enlarge upon this cause, which would afford materials for a volume. It is enough, in this place, to mark the importance which the mere outward observation of practical men has drawn them to attach to it.

The poor laws stand branded by the witnesses as perhaps the most prolific of all the causes of beggary. The object of the poor laws is the very reverse. They are, by this account, the greatest cause of that which they were contrived to prevent. By making a sure provision for every body reduced to want, all motive for begging was expected to be taken away. The legislator looked only to one thing; where he had a great many things to which he ought to have looked.

Mr John Stafford, the chief clerk of the Police-office in Bow-street, said,—"I think it might prevent a considerable number of persons becoming beggars, if there was greater facility given to the magistrates to compel parish-officers to relieve poor persons who are in want, and unable to work or provide for themselves; for, as the law stands now, if a poor person comes to the magistrate to complain that he is in a state of distress, and does not know what to do to obtain relief, that person must apply to two overseers of the poor, who may refuse relief. The magistrate must then summon the two overseers to appear before him; and it is not until after they appear, or have made default, that he is enabled to make any order upon the parish-officers to relieve those persons; so that, in cases where the parish-officers are from home, or when they live at any distance, it requires frequently a day or two before a return to the summons can be procured; then, unless anything can be done in the meantime, the paupers have no means of obtaining relief, but by soliciting charity."

Sir Nathaniel Conant, the magistrate, describes the same evil in nearly the same words. Respecting the beggars produced by this cause he was asked,—"Do you think they constitute a large proportion of the beggars in London?—I cannot state that; there are a great many, almost all the persons not actually known in a parish, who have occasion to apply for parish relief, apply in their last extremity. They are shifted about from post to pillar for two or three days, before they can obtain relief. They beg at the corner of a street; they are taken up by the watchman; and when they are found to belong to a parish, they are let out, instead of being taken to the overseers. I conceive a good many of those who run after the passengers are in that situation. I con-

ceive that, if they could go to the parish-officers at the moment of casualty, they would not be in the streets.

On this head, however, the information afforded by Mr Martin is the most important. It appeared by the Inquiry, of which he was the principal organ, into the State of Mendicity in the Metropolis, that about one half of the beggars in the metropolis in reality belonged to the parishes in the metropolis, and were there entitled to relief. This is most assuredly, in the account of English mendicity, a very extraordinary fact. It is worth while to give the proportions, as they exhibited themselves upon this Inquiry :

CLASS I. PAROCHIAL INDIVIDUALS.

Of Home Parishes; inclusive of about - - -	1,384 children,	about	2,231
Of Distant Parishes; inclusive of - - -	489 ditto	- -	868
Total Parochial Children, about - -	—— 1,873		——
Total Parochial Individuals, about	-	-	3,099

CLASS II. NON-PAROCHIAL INDIVIDUALS.

Irish; inclusive of about	1,091 children,	about	1,770
Scotch; inclusive of -	103 ditto	-	168
Foreign; inclusive of -	29 ditto	-	59
Total Non-Parochial Children, about	—— 1,223		——
Total Non-Parochial Individuals, about -	- -	- -	1,997
Total Children on the 2,000 cases, about - -	3,096		——
Total Individuals on the 2,000 cases, about	-		5,096

Mr Martin observes, " It may appear extraordinary, that the parochial poor should be found to furnish above one half of the general mass of beggars in the metropolis. There are, however, two causes particularly affecting the parochial poor, which have doubtless contributed to reduce many of them to a state of beggary; viz.

" 1. The practice, generally prevailing in the metropolis, of refusing relief to paupers out of the work-house ; and,

" 2. The want of a provision by law, to direct, in particular cases, adequate relief to parochial poor, not resident within the limits of their legal settlements."

It was observed to him, " If it be real distress and not imposture, it should appear that the proper place to apply for relief would be the place of their own settlement ?—It is astonishing how ignorant the poor people are. A great many live in a contiguous parish to that to which they are chargeable, then they are afraid of the law which directs they should be either imprisoned or whipped, or removed home, in case they apply for relief; and some, who have been in better conditions in life, are very delicate in making their distresses known at all.

" Have you ascertained that ?—Yes ; even when I have written, I have frequently found the testimony in some degree corroborated I have received before ; there may have been a variation in a few circumstances, but the general statement has been often true in those cases with which the committee would be most surprised. A woman mentioned a great deal of property abroad (I think in one of the West India Islands) some time ago; I found there was ground for a great part of what she said, but not the whole.

" You think those persons did not know where to apply, till you informed them ?—In many instances they did not know how to apply, or they have been so intimidated by the letter of the law they were afraid.

" Do you think a large proportion of those who applied, became beggars and applied for relief to you, because they did not choose to go to their parish ? —I think there were some, but their motives for that were very various ; in many cases it was entirely timidity.

" You have mentioned in your printed letter of 1811, as one of the causes for beggary, the want of a provision by law to direct, in particular cases, adequate relief to parochial poor not resident within the limits of their legal settlement; what do you mean by that ?—I mean, that supposing there is a man belonging to Liverpool who is a coachmaker's smith for instance, or in some employ in London, and that he falls into temporary distress by sickness; the distress of that family is enhanced, and often goes to the excess of making the wife pawn even the working tools of her husband : if they could immediately go to any magistrate, and claim the necessary relief, to be afterwards refunded by their parish, that distress would be prevented."

To Mr Colquhoun, the magistrate, it was observed, —" You have given it as your opinion, in your *Treatise on Indigence*, that among the causes of vagrancy is the hardship and dread of removals ?—I look upon the removal as one of the greatest evils attaching to the pauper system; if that could be done away by legislative regulation, so as to let the burthen fall equally upon the country at large, that would do more to reduce the rates than any thing else : it is a lamentable thing. I know in the year 1800, that in Braintree and Bocking in Essex, although the average of the whole country was not above 5s. 6d. in the pound, they paid actually 40s. in the pound for poor rates, which amounted nearly to a disinherison of property, in the hands, perhaps, since William the Conqueror, of some of the proprietors ; and I know of property which would let for L. 200 a year in any other part of the country, letting for L. 20 : And I remember another instance, of a person who had established a nursery ; he was rated for that nursery L. 70 a year ; it had cost him L. 800 ; and the question with him was, whether it would not be better to abandon it than sustain the burthen. Wherever you see in England the finest surface of country, such as Hertfordshire, and all the southern counties, there you have the greatest portion of poverty : In Sussex, by the last returns, it was 25 in the hundred, that was, a fourth part of the population ; in Cumberland, five ; in Lancashire, where we should expect more poor than any other, from the fluctuation of labour, 17.

" Do you conceive, that the system of removals at once adds considerably to the expence of the rates, and is a great grievance to the morals of the poor ?

—That it degrades the poor to a very great degree is certain; and that it adds to the rates, but mostly in the metropolis. The managers of the poor are very willing, thinking to get rid of them in a short time, to maintain them, rather than send them to a remote quarter; if it is within 20 or 30 miles, they will remove them, but if it is 200 miles off they do not go to the expence.

"Then they must have the paupers perpetually upon them?—They are in hopes of soon getting rid of them; they often go into the house from the sickness of the head of the family, or from various casualties; they are in hopes things may come round."

Of the existing system of extraordinary laws concerning the poor in England, that part which relates to the whipping and imprisoning of persons found soliciting alms, is represented by the witnesses as one of the grand sources of evil; because it is a law which the present state of humanity will not allow, in ordinary cases, to be executed. The whipping is regularly and totally disused. The putting a wretched being into an English prison is not a way to elevate his mind, and place him above the base thoughts of beggary. It is likely to make him more regardless of all moral, very often of all legal restraints; and where he went in a beggar, to come out a thief. Upon the atrocious cruelty of driving a wretched creature to beggary, in the way explained above, by refusing prompt assistance, and then whipping or imprisoning for an act of such necessity, no comment is required.

Into the mischievous tendency of the principle upon which the system of the English poor laws is built, holding out a premium for worthlessness, and for that excessive multiplication of the people, to which a state of general wretchedness is attached, we shall not at present enter. It will come to be considered, where THE POOR, and the policy regarding them, become the subjects of discussion. What, in this place, chiefly calls for attention, is the course of procedure and detail, in the hands of the parish officers; not as a system of waste and of oppression upon the contribution, nor as a system of tyranny and vexation to the paupers, but as a mode of making beggars. This they do, by their modes both of giving and withholding relief. They give it under such circumstances as to make people fly from it to beggary; they withhold it in such a manner as both to compel and seduce them into beggary. Mr Gurney was asked,—"What is the police establishment of your parish?—We have four beadles and six constables, besides special constables occasionally; but there is a great terror and alarm on the minds of the parish officers of all the parishes, lest the work-house should be overstocked, and lest the parish should be burthened; and, as long as persons get their livelihood without looking to them, though it is by pilfering, unless they actually know that they are pilfering, they take no notice. I have often thought that if many of our poor laws were imperative, instead of permissive, it would be useful; and I am afraid many of the parish officers are ignorant of their duty, as well as the beadles and constables.

"Do you know whether persons confined in the work-houses, and relieved there, are ever let out of those work-houses for the purpose of begging, in the course of the day?—They go out on the Sunday generally, and I believe many of them beg, indeed I am pretty sure of it."

As a cause of beggary, it is necessary here to mention *early and improvident marriages*, and all those other proceedings which tend to increase procreation beyond the measure of subsistence, and thus to keep the great mass of the people sunk near to the level of mendicity,—a proximity from which, by the slightest accident, many of them are continually falling down to it altogether. That this is the grand medium through which beggary is produced, it is needless to offer any proof. The mode in which the principle of population, when injudiciously encouraged, instead of being wisely restrained, operates to the degradation of the people, has been already, in part, explained; and it will be still farther elucidated in a subsequent article of this work.

Among the causes of beggary in England, one may be regarded as pretty remarkable, that is, *Ireland*. Ireland is one of the greatest of all the causes of beggary in England. Considerably more than one-third of all the beggars in the metropolis appear to be Irish. Of all human beings in any part of the globe, the mass of the Irish appear to be in the most deplorable circumstances, whether their moral or physical situation be considered; and that under a government regarded as the best in the world. The art of making governments efficient to the purposes of government is, therefore, still but imperfectly understood.

Some of the witnesses, Mr Colquhoun in particular, bring forward a very important subject. They give the state of the criminal laws as one of the chief among the causes of mendicity.—"About 5000 individuals," he says, "are vomited out of the jails, without character. These people come on society, without any asylum provided for them. If such an asylum could be established, I think, in a very short time, it would relieve the town of a great many of the beggars." The operation of the penal laws upon the moral state of the people is a field of inquiry far too extensive to be introduced into the present article. That an ill-contrived system of correction for offences may degrade the minds of a people, destroy their sensibility to moral considerations, render many of them incapable of that self-esteem, on which the abhorrence of becoming a beggar is founded, nobody can help perceiving. That a great part of the British system of penal law is infected with this tendency, has long been the complaint of discerning and philosophic minds. The public is not a little indebted to the popular writings of Mr Colquhoun, for the degree of attention from men in power which it cannot long be hindered from receiving. Another place in this work will be found for giving to the subject that degree of elucidation which it so highly deserves.

Of all the causes of beggary, *war* may undoubtedly be assumed as one of the most extraordinary. We have already seen in what manner the people converted by it into soldiers swell the ranks of mendicity; but this is only a small part of the deplorable effects. It brings the condition of the whole of the

labouring mass down nearer to the mendicant level; and, of course, a new and additional portion down to it altogether. This it does by the consumption which it produces. Exactly in proportion as money is spent upon war, exactly in that proportion is the means of employing labour, that is, of buoying up the condition of the people, destroyed; exactly in that proportion must the people, *cæteris paribus*, sink. These are conclusions which may be regarded as scientific, and which will never be called in dispute except by those who are ignorant of the subject. It is not impossible for war to be accidentally accompanied with circumstances which counterbalance this tendency, even in respect to wealth; but this is exceedingly rare. The great men very often gain by war: the little almost always lose.

There is one other cause of mendicity, which it is incumbent to mention, because it really includes all the rest; but it can be very little more than mentioned, as it is far too extensive for elucidation in this place. This cause is *legislation,—bad legislation*. An argument, which, though it is too general deeply to impress a mind unaccustomed to generalize, is in fact almost demonstrative, may be given in a few words. Perfect legislation, a legislation capable of turning to the best possible account the command which in this world man possesses over the good things of life, would so conduct society, that, as there would be scarcely any individual who would not, by his moral qualities, deserve, so there would be not one who would be left without the means of corporeal well-being. If this proposition be correct, it follows, as an unavoidable consequence, that every beggar who exists is, in some way or another, the effect and consequence of bad laws. Exactly in proportion as we can make our laws do more of that which all laws ought to do, we shall diminish the number of those who approach the level of mendicity; and at last dry up every source from which it springs. And in the meantime, exactly in proportion as a greater number of the mass of any people are either at, or approach to, the level of mendicity, in that proportion infallibly may the laws be pronounced to be bad.

Effects of Mendicity.

9. We have now stated what the present occasion appears to require, on the subject of the *causes* of mendicity. We proceed to the *effects*, which, being a much less complicated subject, will be much more quickly dispatched.

The effects may be considered as bad, first, in respect to the beggar himself; next, in respect to the community.

With respect to the beggar himself, they are bad exactly in so far as he is less happy in that state, than he would have been in any other in which it is in his power to place himself. If it was not in his power to have placed himself in a situation above suffering to a greater degree for want of the means of well-being, he suffers nothing bodily; perhaps he even gains, if the bodily pains of begging are less than those of the labour to which he would have been doomed. He may suffer in his mind, by the sense of degradation. But when that ceases to be an object, this pain is at an end. In as far as he is likely to be more intemperate as a beggar, he injures his health, and destroys the pleasures of sympathy. And in as far as he is less religious than he would otherwise have been, he is a loser in respect to the hopes which religion bestows.

If he has fallen to beggary, by his misconduct, from a superior state, in which he would have enjoyed more happiness; of this loss, whatever it is, beggary is not the cause, but the previous misconduct. The question is not, what he would have been, had he not lost what he has lost by misconduct, but what, having made that loss, he can now do that would make him happier than begging. If a mind is well educated, and its sensibility to moral considerations acute, almost anything would render it happier than begging. If it is in the brutal state of an uneducated mind,—a mind which has never had its moral sensibility sharpened, few things would render it happier that did not afford it in greater plenty the means of sensual indulgence and ease.

These, such as these, are the considerations by which we should endeavour to estimate the loss of happiness which beggary produces to the generality of beggars *themselves*.

Let us next endeavour to estimate what is lost through it by the community to which the beggar belongs.

There is, first, the loss of his labour, provided he was able to work. He consumes without producing. In this particular he is equally mischievous with every useless soldier, every useless functionary of the state, and not more. Not so much, indeed, as often as their consumption is greater than his.

If the beggar is unable to work, the public, in a pecuniary sense, loses nothing by his beggary, because, it being not proposed to let him die of hunger, he would have been maintained in all events.

What remains, exclusive of moral effects, is only the annoyance which is given to the people at large by the solicitations of beggars; by conveying to them disagreeable impressions through their eyes and their ears. We shall not reckon this for absolutely nothing. But sure we are, that all the amount of pain which in a year is produced in this country by that cause is very inconsiderable. There are exhibitions of sores and filth, and a degree of importunity which we can conceive amounting to a pretty serious nuisance. But these things, we see, it is very easy to prevent.

We come now to the moral effects produced by beggary, which, except in regard to the beggars themselves, in which respect they have been considered already, consist entirely in example; in the tendency which the immorality of beggars has to produce imitation.

But it is the privilege of beggars that their vices are not contagious. The vices of the great infect the whole community. The vices of beggars infect nobody but themselves.

We do not think it is necessary to pursue this subject. The evidence appears to be satisfactory, that beggary, when considered as a *cause* of evil, turns out to be a cause of no great importance. Of the inconveniences sustained by the nation, a very

small portion can be traced to beggary. For even the loss of labour, which is the main article, is very inconsiderable, as the number of able-bodied mendicants is very small, compared with that of the very young, the very old, the mutilated, and diseased.

In the case of beggary, as of many other results in an imperfect state of the social union, the disapprobation and hatred of the mind are very apt to be misplaced. We abhor beggary, but it is the *causes* out of which beggary springs, and from which, along with begging, infinite other evils arise, that deserve almost all our abhorrence.

Expedients for suppressing Beggary.

10. We come now to consider the remedies which may be applied to the disease of beggary; the *facienda,* in short, the things to be done for its removal.

The first and most natural course would be to go to the list of causes; the excess of multiplication, and consequent poverty of the mass of the people; the want of education; the poor laws; the criminal code; wars; and in one word including the whole, bad legislation. Take away the causes, and the effect immediately disappears.

As among the causes of beggary, however, there are some, and these among the most powerful, which cannot be easily or speedily removed, it remains to inquire what, in the meantime, can be done to check their operation.

The first question is, what can be done by the operation of the existing laws.

The following testimony was given by Sir Nathaniel Conant:

" You think if there was a strict execution of the laws now in force, the streets might be cleared of the beggars ?—Certainly.

" In what way would they then be disposed of under the existing law ?—If they were taken in the act of begging in an individual parish, they must be sent into the Bridewell for seven days at least; then a pass must be made to the place of their last settlement; if that is not found by the examination of the Justice to his satisfaction, he sends them into the place of their last residence, the place where they were taken; that parish is to fight against them as well as it can, that is, by bribery, if it can be called so, by giving them relief and letting them slip out of doors.

" What becomes of them then ?—Then they begin again; the existing law will clear them, but it is only for a day.

" Then the laws, as at present constituted, are not sufficient for clearing the streets ?—My answer to that would be, that the nature of such a town as this is such, that they cannot be cleared in those intervals which occur between the application and the relief given; there will be distress and hunger, which will drive the paupers to mendicity.

" Then, if they are passed to a parish near to London, they may be engaged in begging again in eight and forty hours ?—Yes, in less than that; and where they are passed to distant parishes, there are perhaps only two or three farms; the occupiers of those farms are very unfit to have the care of such persons, perhaps, from their age or their sex, and very unwilling to have such pensioners.

" Can you suggest any alteration of the law, which would have the effect of clearing the streets ?—I think that might be effected by a strict execution of the existing laws; but that would introduce such a degree of severity as to a considerable part, not perhaps half, that it would be quite as great as the laceration of the mind of the passenger on seeing such objects.

" The question refers to the case of persons returning to their parishes, and then beginning begging again ?—The nature of the legislation of England is, that it always goes upon the idea of the whole, and not of a crowded metropolis; and it supposes the profligacy or industry of each individual to be known.

" You were understood to state, that when a person was taken up, he was sent to Bridewell for seven days, then passed to his parish, and that, if that parish was in London, he then returned to a state of mendicity. Can you suggest any alteration which would prevent the beggar who had been in Bridewell, and who had been passed to his parish, returning to a state of mendicity ?—Parliament might compel the parish to maintain them until they are enabled to obtain their own livelihood, according to their age, or strength, or sex; but nothing less than that would do, for the person goes out without clothing sufficient for a decent occupation."

Sir Nathaniel had stated, that he did not give orders for taking up the beggars with all the strictness of the law, and gave the following as his reasons:—" That if I did give those orders this morning, I should have those that are impostors all run away into the next street, only so to elude the people to whom I gave the directions; and I should have blind and imbecile creatures, who had no claim at all upon the justice of the parish in which they happen to be taken, though that parish would, in the first instance, be made liable to them, if I passed them into that parish after sending them to prison for a week, which the Act of Parliament necessarily includes; for no pass can be made till they have been in prison a week. If they were passed into that parish, the parish-officers would, in their policy, and in justice to their neighbours, say, " Why do you come here? you come here as a beggar, and have been punished; here is a shilling, go about your business, and get yourself conditioned in some other place." They would walk down below the Tower, and beg there for another week, and then get up again into Westminster, and continue the practice of begging, having no settlement perhaps.

" Supposing the magistrates were to follow the letter of the law, might not they be all removed from the neighbourhood of the metropolis ?—I think they might; I think the practice established at Edinburgh might be practised here, *but with dreadful cruelty to two-thirds of the persons subjected to that mode of subsistence.* In Edinburgh, they act with extreme severity to every person found in a state of mendicity."

Sir D. Williams gave the following testimony:—

" Do you take any steps, through the medium of your officers, to take up beggars ?—We have given instructions generally to take up all beggars; and it

has been done also by several parishes in the neighbourhood, who have directed their beadles to take them into custody.

"Is it your opinion, that if the same mode was pursued by the other magistrates in different districts, that many beggars would be prevented from pursuing that course of life?—There can be no doubt of it.

"You consider the present laws sufficiently strong, if those laws were put in force?—No doubt.

"And that if the magistrates were to put the law into force as it now exists, public begging might be prevented?—There can be no doubt of it.

"You consider that the laws might be so far put in force, as to clear the streets of beggars; have the goodness to state to the committee the process which takes place with the beggars found in your district?—Any person has a right to capture a beggar in the act of begging; he is to take him before a magistrate; the magistrate, by the confession of the party himself, or the oath of another party, is bound to pronounce him a rogue and vagabond, and send him to the House of Correction for the county of Middlesex; there he remains seven days, and is passed by the pass-master of the county to the next parish leading to his settlement, and so forward till he arrives at the place of settlement; and for which the person capturing the mendicant is allowed by law 5s.; there is a premium for it.

"Supposing the parish to which he actually belongs remains within your district, or is that in which he is found begging; there is nothing to prevent him, on his return, resuming the same practice of begging?—The law will prevent that, by sentencing him as an incorrigible rogue, to six months imprisonment, if he has been pronounced a rogue and vagabond under the first charge.

"Are those steps frequently taken by you?—They are brought before the Court, and the Court adjudges them to a further imprisonment.

"How long do they remain there?—Seven days in the first instance, and six months in the second."

Patrick Colquhoun, Esq. to whom, primarily, his Country is indebted for all the knowledge it has recently gained, and all the improvement it has made in Police, delivered the following testimony:—"Of late it is inconceivable the number that have received passes from the magistrates to go to their different parishes; which we give now, though directly in opposition to the Act of 1792, which requires they should be previously whipped or imprisoned a certain number of days, and then passed as vagrants to their parishes; that Act has been found impracticable. It arose from the Lord Mayor and the magistrates giving innumerable passes, of which I am afraid many make the very worst use; but we are very glad to get them out of the town, that they may be subsisted in the quarters to which they belong, or where they have friends; in that way we are relieved of a very considerable number, who must otherwise beg in the streets.

"Do you conceive that the laws as they at present exist relative to beggars, if put into due and strict execution by all the magistrates in London and its vicinity, would be sufficient to clear the streets of beggars?—I do not indeed; there have been attempts made at different times, and they have all failed. I think the Act of 17th Geo. II. totally inadequate to the purpose; it is loosely worded; it is not at all adapted to the present state of society; and that Act ought to be revised from the beginning, and adapted to the present state of society.

"Do you mean individual and separate attempts?—I mean to say various attempts have been made, by taking up the beggars; the expence is enormous on the county rate. I believe at one time there was more than L. 100 paid to the office I belong to, in the course of the sessions.

"If all the magistrates were to unite, the magistrates of the city of London, the magistrates of Westminster, and the magistrates of the vicinity, to put the laws in execution, do you think that would be successful?—As far as my judgment goes, if the whole were to join their efforts it would not succeed."

The beadles complain that when they take up beggars the magistrates discharge them. One of the beadles of St George's, Bloomsbury, said, "I took up a man yesterday that I observed knocking at every house, regularly, in Bloomsbury-square, two or three days ago. He was again yesterday taking every house regularly; I waited till the servant came to the door, and he then put a petition into her hand; I took the petition from him, and took him to the watch-house. I found three copies of the petition upon him. I took him to the office in Hatton Garden, and the magistrate discharged him.

"Did the magistrates examine you upon your oath?—They did; and I told them I had removed him out of Bloomsbury-square, three days before, in consequence of great complaints of the inhabitants, that those persons were suffered to be about.

"You stated upon your oath, to the magistrate, that you believed him to be a common vagrant?—Yes; he paused a quarter of an hour upon it; and he said, the prison was so full of people that he thought it not right to commit him there. He talked of sending him to the New Prison, and the clerk said it must be the House of Correction. I told him I should not object, if he thought proper to discharge him, which he did. The magistrate told me, if I saw him again, I might bring him. I could have taken four beggars up on Sunday, but if we take them down they discharge them.

"That is the practice of the magistrates?—It is. I have taken many and many down, and they have been discharged; and my brother beadles will give the same testimony."

Mr Mills, a gentleman who had been Overseer of the parish of St Giles, stated, "We used to take them to the magistrates, and take the recourse the law provided; but, in fact, the magistrates themselves would have loaded the prison, they were so numerous. In our parish there was no end to the commitments which would have taken place. I have sat with my brother officers from two o'clock in the afternoon till eight in the evening, constantly relieving those persons."

It thus, we think, sufficiently appears, that the law for the compulsive prevention of beggary cannot be executed, or, more accurately speaking, it is unfit for execution; it cannot be executed without

producing a much greater quantity of evil than it seeks to remedy; and therefore the magistrates take upon them, without scruple, to violate it, and leave it without execution.

Of the things to be done, one, then, most obviously suggested, is *a review of the existing laws* which relate to beggary; the repeal of all the enactments, which are ill adapted to the object in view; and the passing of other enactments which may possess the greatest practicable degree of adaptation and efficiency. Into the detail of these enactments, it is not here the intention to enter, because they must embrace the provision which is made for the destitute; the questions relating to which, we reserve for the article on the Poor.

Another of the remedial operations, importunately demanded, is to make provision immediately for the careful and efficient education of the whole mass of the population, down to the lowest individual. On the potent connection between good education, and that sort of conduct which keeps people above the level of mendicity, as well as on the mode in which education should be provided, our sentiments will be given with more propriety on another occasion.

As the tendency in population to increase faster than food, produces a greater number of individuals than can be fed,—as this is the grand parent of indigence, and the most prolific of all the sources of evil to the labouring portion of mankind, take all possible measures for preventing so rapid a multiplication; and let no mere prejudice, whether religious or political, restrain your hands in so beneficient and meritorious an undertaking. It would be easy to offer suggestions on this head, if we were not entirely precluded from going into detail. It is abundantly evident, in the meantime, that indirect methods can alone avail; the passions to be combated cannot be destroyed; nor, to the production of effects of any considerable magnitude, resisted. With a little ingenuity they may, however, be eluded, and, instead of spending themselves in hurtful, made to spend themselves in harmless channels. This it is the business of skilful legislation to effect.

In cutting off other causes, cut off Ireland; we do not mean literally; but what we mean is, that the mode of governing Ireland should be so reformed, as to make it able to send to England something better than a mass of beggars nearly equal to all her own.

Make a law to prohibit all modes of paying the people, which have an affinity with yielding to the cravings of a beggar.

Take all proper methods of rendering universal and preserving alive that exquisite moral sensibility, which is possessed by so great a portion of your population, and makes them willing to die of hunger rather than beg.

Provide a proper asylum for rearing to virtue the children of beggars; and let no person who begs be allowed, on any terms, to retain power over a single child; that, at any rate, you may prevent any portion of the young from being reared to beggary. This is an easy, obvious, and most important part of a good plan for lessening or extinguishing the evil of beggary.

Reform your criminal code; and cease to deal with offences in such a fashion, as to make the indigence of your people greater, and the virtues less, than they would otherwise be.

Under the head of improvement in the criminal law, it may be fittest to speak of that indispensable instrument for the cure of beggary,—a system of *Reformatories*, or houses in which bad habits may be eradicated and good acquired. On this point, some of the witnesses, whose testimony is entitled to the greatest respect, used a language unusually strong. The chaplain to Bridewell Hospital said, "I have long thought, *seeing so much misery as I have done*, that, as to remedy, very little could be done, unless you deprive the beggars of the pretext of begging; *that* that could be only by *a large penitentiary system*.

"Has it occurred to your mind, that there could be a *Penitentiary* large enough to include all those persons?—I have not proposed one for the whole town, but four or five at different parts of the town.

"Did you propose this for persons having settlements in the country, and others?—Yes; that every person knocking at the door might have admission, and that no person should have a pretext for begging in the streets. If a committee was sitting at either of those Penitentiaries, and work was going on at them, that would relieve from part of the expence; the *great advantage that appears to my mind* is, *the investigation of each case.* I do not know any place in town where that can be done. I have frequently thought, that unless there could be such a system as that to which I have alluded, the clearing of the town is hopeless: The great mass of misery which floats in this metropolis, I am fearful can never be removed, unless there is such a penitentiary system as that to which I have alluded: the two societies established for the reception of such persons are far too confined.

"If one, two, or three large ships could be fitted up with good accommodation, do you think such places could be substituted for penitentiary houses, till the parties were disposed of?—I never but once saw any thing of the kind, and that was at Sheerness some years ago, when I think the sailors' wives lived in two large hulks drawn up on shore; but there appeared to be so much misery and wretchedness, and they were so close and confined, that I did not form a favourable opinion of it.

"The question supposes the ships to be fitted up in an airy manner, with convenient apartments, that would receive nearly as many, at little or no expence to the public, as the Penitentiary House now building at a very great expence?—The penitentiary houses, as proposed by me, would include workshops and rope-walks, and so on."

Mr Colquhoun was asked,—"Do you think there could be any law devised by which there could be a possibility of furnishing relief to that class of persons who may be properly called beggars, by which they could be removed out of the streets?—I think it is perfectly possible to lessen the evil in a very considerable degree, but it must be by legislative regulation, and at pretty considerable expence. The situation of this town, to which so many wander up, is such that there must be an asylum for beggars,

with a species of work-house, or what I would call a Village of Industry, that would apply to all. That struck me so strongly in the year 1792, that I wrote a paper on the subject; and I believe if the war had not broken out, it would have taken place. About 5000 are vomited out of the jails, without character; those people coming on society, it would have been a most desirable thing to have had an Asylum for them; but it was so gigantic a thing, that that prevented its being carried into effect. If such an Asylum could be established, I think in a very short time it would relieve the town of a great many of the beggars; but the magistrates must necessarily have some place to send them to.

"The Committee have been informed, that, within these few weeks, as is customary at this season of the year, there have entered London about 5000 persons of the labouring class, probably many of the mendicant class?—I cannot speak to the number; but I have no doubt of it.

"Would your plan of an Asylum go to the relieving those persons?—It would go to the relieving all persons who are mendicants, or had lost their character, by being committed for petty offences to the different prisons of the metropolis."

This, undoubtedly, is the right idea. Provide a system of Reformatories as perfect as they might easily be made, and you may accomplish every thing. Deprive yourselves of this important instrument, and you can do but little to any good purpose. A more appropriate place for describing this measure in detail, will occur more than once hereafter. We know, however, only one good plan, and that is before the world already, in Mr Bentham's *Panopticon*. Apply this, with the system of management which he has contrived for it, and if you do not extinguish the evil of pauperism, in all its degrees, you will undoubtedly reduce it to its lowest terms.

In the testimony given by the chaplain of Bridewell, as we have seen in the preceding quotation, he mentions, "the investigation of each particular case of beggary," as an advantage of the highest possible kind.

Mr Butterworth said,—"I conceive that no plan of relieving the poor is so effectual as that of visiting them at their own habitations; and even then, inquiry must be made of their neighbours, to know their real characters, as persons in the habit of begging are adepts in the art of imposition."

Mr Cooper was asked,—"In what way do you think poor families may be mostly benefited by the exercise of benevolence?—I know of no way more efficient than that of their being visited and relieved at their own habitations; and, in fact, as far as my observation and experience go, there is no certainty whatever of any donation being properly applied, without investigating the circumstances at their own habitations."

We deem these testimonies of great importance; as we are convinced, that what is here recommended, a distinct investigation of each individual case, rendered co-extensive with the population, would be attended with innumerable advantages.

To render this investigation practicable, without enormous trouble, and, indeed, to render it possible with any tolerable degree of exactness, another and a most important operation is required, subservient to an infinite number of good purposes; and that is, a proper system of registration. The whole country should be divided into sections, containing each a moderate number of inhabitants; the names, residences, and descriptions of the inhabitants of each section should be entered in a public record; and means employed (as much as could be without incurring any serious inconvenience of a different sort) for placing the people of each under the full inspection of one another. How important a check this would be on improper conduct of every sort is intuitively manifest. How easy, too, it would render the business of visitation, and what perfect knowledge it would afford of the circumstances of each individual case, it is impossible to overlook.

The importance of registration was not unknown to some of the witnesses before the Mendicity Committee. Sir N. Conant observed,—"In a town like this, where no creature knows the inhabitant of the next house hardly, or their character, and especially among the poor, the overseers of parishes ready enough at all times to spare if they can, by any kind of indulgence (I was going to say) the parish purse, are always willing to put at a distance every person who applies, being entirely ignorant either of their character or of their necessity. Until they are forced to take them in, and give them relief, they seldom do, unless they know them, and they know very few of the inhabitants even of their own parish, in the very nature of the thing; this applies to any condition of life, and more especially to the poor; that introduces another class of mendicants, which are people deserving of parochial relief, in the interval before they get it. If the paupers apply to-day to the parish officer, being settled in their parish, they are not known to him; and the parish officer either says, he shall make some inquiry; or, that they look strong and hearty, and able to maintain themselves, or that their families may be imposed upon them, and that he shall inquire and see, and they may work."

We find Benefit Clubs, and Savings Banks, held forth as means for the preventing of beggary. But we question, whether the sort of people who apply to savings banks and benefit clubs are apt to become beggars. We see, that those among the common people, who have had any moral feelings implanted in them, will in general die rather than beg. We see also, that the having a provision already made is no security against mendicity, when the mind is worthless; because many of the Greenwich and Chelsea pensioners beg, and are among the most troublesome of all beggars. It would surely not be difficult to find a better mode of paying these pensioners, so as to afford a check upon their vices. Some way might also be found of punishing those parishes, who, when a beggar is passed to them, instantly let him out again, to prey upon the public. When a beggar appears, if it is resolved to suppress them altogether; or when he acts in any such manner as to create a nuisance, if it is only proposed to suppress what is noisome about them; it should al-

ways be easy at the moment for any passenger, or observer, to put in execution the means of taking them up. For this purpose, it would be necessary that a constable or beadle authorized for this purpose should be in every street, and his residence rendered conspicuous to all the passengers.

Under the head of remedies for the disease of beggary, it is necessary to speak of societies for the suppression of it. In the first place, it is abundantly evident, that an assemblage of private individuals have little power over the chief *causes* of mendicity; over wars, for example, excessive procreation, and bad legislation. They can only endeavour to counteract, by such powers as they possess, the operation of these causes. They may, indeed, contribute *indirectly* to the removal of the causes; namely, by holding them up in their true colours, to the legislature, and to the nation. This, it may be observed, in one of the ways in which they may effect the greatest quantity of good; may, in fact, advance with the greatest expedition to the accomplishment of their own end. With the means possessed in this country of operating upon the public mind, and the influence of the public mind upon the legislature, a society of gentlemen, rendered conspicuous by their union, and the beneficence of their proceedings, might, by representations, sufficiently persevering, and sufficiently strong, more especially if the operation was not confined to one society, but common to a number of societies, in numerous parts of the country; effect almost any improvement of which the nature of the case would admit.

Society at Edinburgh for the Suppression of Beggary.

The first idea of a Society of this sort, as far as we know, was started in Edinburgh, and there carried into execution in the year 1813. The sole object of this society appears to have been to try what they could do for the cure of beggary, under the existing laws. There is no evidence of their having elevated their views to the thought of operating through the public upon the legislature, and through the legislature upon the sources from which mendicity flows.

In the sphere which the *Society of Edinburgh* have chalked out for themselves, it is impossible for us not to bestow upon their proceedings the highest encomiums; since they have put in practice, as far as it lay within their power, the principles which we have here recommended as the groundwork of reform.

In the first place, the *Visitation principle*:—"The basis of the whole plan," says their Report, "was to be investigation, and personal inquiry."

Secondly, the *Registration principle*:—"For the sake of facilitating the task of making such inquiries," continues the Report, "and the labour of superintending the poor, as the only means of preventing fraud and imposture, it was necessary to divide the city into separate wards or districts." From the want of legislative powers, however, it is abundantly evident, that they could perform the work of registration very imperfectly; were obliged, in fact, to content themselves with the registration of those persons exclusively who applied to them for relief; and instead of placing them effectually under the superintendence of the district itself, to take the labour of superintendence wholly upon themselves. If the business of registration, thus imperfectly performed, is yet an important instrument, how much would that importance be increased, if it were performed completely by legislative regulation.

Thirdly, the *Reformatory*, or *Employment principle*: The society is divided into four committees, of one of whom the business is to find employment for those of the applicants who are able to labour. It is evident under what prodigious disadvantages they carry on this part of their beneficent work. To perform it with any degree of completeness, a great establishment, such as those which have been called penitentiaries, houses of industry, reformatories, or panopticons, is required; an establishment in which different species of work may be carried on with all the accommodations which belong to them; in which the parties may work under the most complete superintendence; and in which they may be as completely as possible exposed to the operation of all the salutary motives which can be brought to bear upon them.

Fourthly, the *Education principle*: The children of the beggars are clothed, and sent to a Lancastrian school; and so important is this part of the business of the society accounted, that one of the four committees is wholly employed in conducting it.

What the Society professes is, to provide subsistence for all those who really are deprived of it, and of the means of providing it for themselves; and upon the strength of this undertaking the police of the city prohibit begging, by imprisoning and removing the beggars.

The only question which applies to this expedient regards the power of the Society to accomplish all which they undertake. If they can make provision for all who really and truly are in want; to prohibit begging is then to prohibit imposture, and can produce nothing but good. And if, along with this, they are able to make the distinction completely between those who are and those who are not able to provide for themselves; and to draw the benefit of labour from all who are capable of it; as far as there is any evil in mere begging, beyond the evil of being reduced to the begging condition, which is the principal, it is removed. It is not absolutely impossible that such an expedient as that of the Edinburgh Society, at one particular place, and one particular time; namely, when taken up with extraordinary ardour, owing to some particular concurrence of circumstances,—as in Edinburgh at the era of a new System of Police; or to the ardour of one or more individuals of sufficient influence to set a fashion, may, to a considerable degree, succeed. But it is abundantly cetrain, that it is not calculated for general or permanent use. How could it be applied to London, for example?—Besides; a great national benefit can never rest with safety on any thing so precarious, as the chance of extraordinary virtue in particular men. (F.F.)

Bejapour.

BEJAPOUR. The great peninsula of India is divided into several extensive kingdoms, which are partitioned into subordinate states of different denominations. Some were powerful sovereignties, enjoying a distinguished rank in the scale of nations, and subsisting during many centuries in splendour, as the empire of the Moguls; while others, as the Mysore, constituting the dominions of Hyder Ali, and his son Tippoo Saib, were of more recent formation, and owed their aggrandizement to the weakness of their neighbours. Bejapour is a large province in that part of India called the Deccan, extending from the 15th to the 19th degree of north latitude, and intersected by the 75th degree of east longitude, passing nearly through its centre. It is calculated to be 350 miles in length, by at least 200 in breadth, and thus is about equivalent to England in size. This province is bounded on the north and east by the provinces of Arungabad and Beeder, on the south by North Canara and the river Toombudra, and on the west by the sea. The western coast, for the space of 200 miles, is denominated Concan, forming a subordinate district, which has been long noted for the piracy of its inhabitants, who find secure retreats in the numerous bays and inlets on the shore, and a ready market for their plunder.

Boundaries.

Rivers.

Bejapour is watered by many fine rivers, of which the principal are the Toombudra, Krishna, Beemah, and Gutpurba. The last exhibits a tremendous cataract, perpendicularly precipitated from a rock 174 feet high; where the river, during the rains, is 507 feet wide. A great range of mountains, being the continuation of the western Ghauts, traverses the province 40 or 60 miles from the sea, through which are several passes of long and painful ascent, leading to the more level parts of the country. Their height intercepts the passage of the clouds, and numerous streams pour down from them, which, in the wet season, are swelled into irresistible torrents, spreading over the plains; but where low and smooth, they are crossed by travellers in large round baskets, covered with hides, as a substitute for boats.

Soil.

The fertility of the soil is various; but except in the rocky and mountainous places it is in general sufficient to afford an ample subsistence to the inhabitants. Nevertheless, they are sometimes visited by famine, resulting as much from the injuries of warfare as the effects of climate. Provisions are both cheap and plentiful. The horses reared on the banks of the river Beemah are highly esteemed, and constitute the best cavalry of the Mahrattas, who are eminently distinguished for that kind of military force.

Population.

The population of the province is calculated at 7,000,000; of which, about a twentieth part is supposed to consist of Mahometans; the great body follow the doctrines of Brahma. They affect observance of their religious customs in the utmost purity; they totally abstain from animal food, and some of them even scruple to subsist on roots. But they are said, notwithstanding, to be rather in disrepute among their own tribes in different parts of India. It is undoubted, however, that there are some devotees in the peninsula, who, far from crediting that all things are created for the use of mankind, reject every species of subsistence but milk, that nothing more gross may form in their intestines. Cows, it is well known, are objects of veneration, and in some places, beef is never used except by certain lower tribes of Hindoos; but particular towns have the privilege of killing beef for sale. Religious prejudices are carried to such an extraordinary height in India, that the lowest ranks of those sects which pique themselves on purity, would refuse to eat with sovereigns whom they did not esteem of an origin equally pure. Widows in Bejapour burn themselves with the bodies of their husbands, and a year never elapses without witnessing some of these horrible sacrifices; the offspring of the most barbarous principles of delusion. Bramins are found in this territory weak enough to maintain, that the ground they occupy is so sacred that it will bear only a particular species of shrub, which, in the fervour of their zeal, they have consecrated. It is likely that the Mahometan religion was much more in observance formerly than at the present date, from the number of mosques seen in various stages of decay.

Cities.

There are many large towns and celebrated cities in this province, which was once a great and independent kingdom. Of these, the principal are Bejapour, Poonah, Satarah, Hubely, Huttany, Punderpoor, Darwar, and Meritch, for the most part populous and wealthy places. Bejapour is a city of such immense extent, that, were we not in possession of recent observations, what has been said regarding it might be supposed altogether fabulous. It is situate on a fine plain, in a fertile country, and now rather resembles the ruins of several separate and detached towns, than the remains of a single city. Its name, in the native language, signifies *impregnable*; and it may be said to consist of three cities contained within each other. The exterior is encompassed by a wall many miles in circuit, fortified by capacious towers of hewn stone, at intervals of 100 yards, and secured by a ditch and rampart. The interior, or second city, which is the fort, is not less than eight miles in compass; and the third or innermost, contained in it, is the citadel or strong-hold, which is a mile in circumference. But the whole are approaching to a state of decay, although the massy materials of which they are composed will long resist the ravages of time. The natives affirm, that, when the city was in its full splendour, it contained, according to authentic records, 984,456 houses, and 1600 mosques or temples. How far the former number is exaggerated we have no means of determining; the latest visitors are of opinion that the number of mosques and temples may have been as stated. Without supporting the affirmation of the natives, we may observe, that some great cities of the east are, in fact, an assemblage of towns and villages encompassed by a common wall, and even include gardens and cultivated fields. Besides, with regard to Bejapour, we learn, that, in the year 1689, when invested by Aurungzebe at the head of his army, 15,000 cavalry could encamp between the fort and the city wall. A mile and a half distant from this, a town, called Toorvee, has been built from part of the remains of the city, amidst magnificent piles of ruins.

Bejapour.

The fort is approached from one side, through a

Bejapour. neat small town on the south-west. The ditch, originally a formidable obstacle, is excavated from the rock on which it stands. The curtain or wall is of great height, probably 40 feet, entirely composed of huge stones, strongly cemented together, and frequently ornamented with sculptures of lions and tigers. It is flanked by numerous great towers, built of similar materials, and some with ornaments resembling a cornice at the top. The fort has seven entrances, five of which are in use, and the other two are shut. On the south-west side it is entered by three gates, near to the innermost of which is a tank, or artificial pond, about 300 feet long, by 225 broad, environed by steps descending to the water, and surrounded by an inclosure of fine stone houses, through which it is reached by an arched passage 50 feet wide. Several distinct towns are contained within that part called the fort, with neat bazars or market-places; and there are many splendid edifices, on which all the embellishments of eastern taste and magnificence have been lavished.

Among the first which claims admiration, is a great mosque, commenced by Mahomet Adil Shah, king of Bejapour, who died in the year 1660, and continued by his successors. The main body extends 291 feet by 195, and there is a wing projecting from each end 219 feet long by 45 broad, inclosing together, with the main body, a large reservoir and a fountain. Five lofty arches spread along the whole extent of the eastern front, under the centre of which are a few steps leading up into the building. The interior is richly ornamented with passages from the Koran, with the names of God, Mahomet, or the Caliphs, in relief; the groundwork enamelled, and the letters polished or gilt. In a mausoleum, 153 feet square, the body of the Shah reposes. There are circular buildings on the external angles, which, as well as the wall, rise about 100 feet high. Its grand entrance is very lofty, and highly adorned with sculptured inscriptions, and other ornaments. This sepulchral chamber is surmounted by a great dome, whose internal diameter is 117 feet, a vault under the centre of which contains the royal remains. But the dome is much neglected, and shrubs and weeds find root in it, which must occasion premature decay. The whole is executed in a style of plain and simple grandeur.

Without the fort, in the exterior city, there is a mosque of still larger dimensions, and the mausoleum of Ibrahim, another king of Bejapour, who seems to have completed it about the year 1620. The mosque is 390 feet in length, by 156 in breadth. Fronting it, at the distance of 40 yards, is the mausoleum, 57 feet square, inclosed by two virandas, the inner 13 feet broad and 22 feet high, the outer 20 feet broad by 30 in height, supported by seven arches in each face, which are beautifully ornamented above. The sides of the chamber are sculptured in the most elaborate manner with flowers on a blue ground resembling enamel, and sacred passages, as before, in relief, cut out of a black stone, and polished as highly as a mirror. The doors are studded with gilt knobs, and the doorways are adorned with a variety of ornaments exquisitely executed. Around the southern entrance, there is a mystical tetrastich, signifying that the cost of the edifice was equivalent to L. 700,000, and it is said that 6533 workmen were employed on it 36 years, 11 months, and 11 days. Six graves are inclosed by the sepulchral chamber, which are always covered with a fine white cloth. Above it is a cupola: and the mosque is surmounted by another immense dome, supported on arches. The whole edifice is finished with a profusion of ornaments in the highest style of embellishment. There is also in Bejapour the tomb of Aurungzebe's queen, who was mother of his favourite son, consisting simply of beautiful white marble.

This city, as we have already seen, is equally distinguished by its fortifications. Indeed, everything here appears on a gigantic scale; and among the most remarkable objects, may be enumerated some enormous cannon, said to be twelve in number, deposited in different places. Many more were originally employed in its defence. Three of these are particularly described; the first, contained in a great tower on the south-east side of the fort, is a Malabar gun composed of iron bars hooped together, and hammered smooth; its dimensions are as follows:

Length, - -	21 *Feet*	5 *Inches.*
Diameter at the breech,	4	5
Diameter at the muzzle,	4	3
Calibre, - -	1	9

The second gun, which is of the same construction, and called in the language of the country the Farflyer, is contained in a lofty tower near the western side of the fort; its dimensions are,

Length, - -	30 *Feet*	$3\frac{1}{2}$ *Inches.*
Circumference at the breech, -	9	2
Circumference at the muzzle, -	7	7
Calibre, - -	1	1

But the third is of brass, and fixed on a great iron ring inserted in the ground, and grasping its trunnions, in the manner of a swivel. It is contained in a tower still larger than the former, on another side of the fort, and its dimensions are not inferior, though in none of the modern proportions;

Length, - -	14 *Feet*	1 *Inch.*
Diameter at the breech,	4	$10\frac{1}{2}$
Diameter at the muzzle,	4	8
Circumference in the middle, - -	13	7
Calibre, - -	2	4

This enormous gun is called *Moolk e Meidan*, or the *Sovereign of the Plains*, and it would carry an iron shot of 2646 lbs. It is beautifully wrought with several ornamental devices, particularly about the muzzle, and its polish is almost equal to that of glass. Several Persian and Arabic inscriptions appear upon it in elegant characters, one of them, according to English travellers, purporting that it was cast by Aurungzebe, the famous Mogul emperor, on his conquest of

Bejapour. the city in 1689; but we observe that some eastern historians affirm that he only substituted this inscription on erazing a previous one, and that during the siege of Bejapour, the shot of *Moolk e Meidan* damaged the mosque and mausoleum of Ibrahim Adil Shah. This gun had a companion of equal size, called *Kurk e Bedjlée*, or *Thunder and Lightning*, which was carried to Poonah, and is supposed to have been melted down. Probably no European cannon of equal size are known; *Mons-Meg*, a celebrated gun, now in the Tower of London, whither it was removed from Edinburgh Castle, is only of 20 inches calibre, and tapers downwards.

The inner fort or citadel, though a mile in circuit, is compared to a speck in the space occupied by the outer one. It is a place of great strength, consisting of a curtain, frequent large towers, a ditch, and covert way; the whole composed of massy materials, well constructed. The ditch, which was formerly supplied with water, is in most parts 100 yards wide, but the rubbish now filling it precludes any calculation of its original depth. The citadel itself is gained through several gates; but within it is a heap of ruins; and only one edifice, a beautiful small mosque, is in complete repair. Here were the palaces of the kings; the front of one of which is formed of three arches; that in the middle 87 feet wide. It has been observed, that all the arches in the city of Bejapour are Gothic, except those in the remains of a fine black stone palace in the citadel, built by Ibrahim Shah, where they are elliptic.

These are only a few of the public edifices contained in this extensive place, situated amidst piles of ruins, which appear at the interval of miles. A minute and accurate traveller has remarked, "that none of the buildings here described, the palaces in the fort excepted, have in them any wood; they are in general constructed of the most massy stone, in so durable a style, that one is almost induced to suppose, that the rudest hand of time, unaided, could scarcely have effected such destruction, nor could it seem that such ponderous gates were reared by the hands of men. The massy materials of some, the minute exquisite workmanship, and still greater durability of others, the ingenuity of the projectors, the skill of the artists, everything, indeed, that adorns the science of architecture are here united in so many instances, that the mind can scarcely realize the grandeur and magnificence of the objects that are in every direction scattered so profusely. On the other hand, such mountains of destruction, noble even in ruins, dictate the idea, that it proceeded, not from the ordinary revolution of time and things, but that they were rent from their foundation by some violent convulsion of nature." Until very lately, the most inaccurate opinions prevailed in Europe regarding the site and extent of Bejapour, which was better known by the name of Visiapour.

Poonah. Poonah, the capital of the formidable empire of the Mahrattas, also stands in this province; at a place where the rivers Moota and Moola meet, and form a united stream called Moota-moola. Unlike the former, it is an open and defenceless city, occupying a superficial area of about two miles square, and washed on the north by the river Moota; there about 600 feet wide, but shallow in the dry season. A bridge across it was commenced some time ago by the Peshwa, or Mahratta chief; but the decease both of himself and his successor having followed, the undertaking was abandoned as displeasing to the gods. The streets here are named after mythological personages venerated by the Hindoos, adding the termination *warry* to their proper appellation; and the divinities, with their monstrous and grotesque appendages, are sometimes painted on the exterior of the houses. There is an ancient castle in Poonah, surrounded by lofty strong walls, with only one entrance, and protected by four round towers, wherein some members of the Peshwa's family reside; but he occupies another residence, and, not long since, he had directed a palace to be erected by British architects. The population of Poonah is estimated at 100,000 souls. Formerly, the Mahrattas, on invasion of a hostile force, did not consider the preservation of so defenceless a place of importance to their power, and they have themselves destroyed it, retiring to Poorunder, a fortress on a mountain, about 18 miles distant, where the archives are deposited, and where some of the principal officers usually reside. Its prosperity is said to have been retarded by great assemblages of people who convoke for the purpose of celebrating some religious festivals, and marking their retreat, when these are over, by indiscriminate pillage and depredation. Poonah is 98 miles from Bombay.

Punderpour. Punderpour is a flourishing and populous city, 86 miles south-east of Poonah, situate in a fertile and pleasant country, on the river Beemah, by which it is sometimes inundated. Though not of great extent, it is regularly and well built; the streets are broad, paved, and adorned with many handsome houses, the first storey consisting of stone, and the second of red brick, which has a very agreeable effect. The Peshwa and most of the principal members of the Mahratta government have elegant mansions in Punderpour, whither they retire as a relaxation from the fatigues of business. Besides native products, many articles of European manufacture are to be obtained here, as the merchants have connections with those of Bombay.

Hubely and Huttany. Among other towns in the province of Bejapour, there are two of considerable size, called Hubely and Huttany. The appearance of the former, which is situate in a district well wooded and watered, and in a high state of cultivation, bespeaks industry and comfort. An extensive inland traffic is carried on by its inhabitants, and a commercial intercourse is conducted with the east, principally through the medium of Goa, whence, in return for sandal-wood and elephants' teeth, they receive raw silk, cotton, and woollen stuffs. The bankers, who are rich and numerous, extend their transactions to Hyderabad, Seringapatam, and Surat: and the markets are so well attended, that the streets are scarcely passable from the crowd. There are two forts here, now very defenceless, from nearly being environed by houses; but the town has frequently been an object of competition between contending

Bejapour.

powers. Huttany is inclosed by a wall and ditch, and also has a fort, which is incapable of standing a siege. In the year 1679, it was taken from the Mahrattas, and the enemy proposed to sell all the inhabitants for slaves; but this was not carried into execution. It is now large and populous, carrying on a great manufacture of silk and cotton; and an extensive trade in these articles, and also in grain, with the north of India and elsewhere. The natives are celebrated for their courtesy to strangers, whom they apparently are desirous of impressing with a high opinion of their wealth.

There are many strong forts in the province, smaller, and thence more capable of protracted resistance, than those already named. Such is Darwar, or Haserabad, a place of great strength, inclosed by a wall and ditch. In the year 1790, it was besieged by the united forces of the British and Mahrattas, amounting to 40,000 men, and surrendered by capitulation, chiefly from scarcity of provisions. This fort stands in a territory called Darwar, which is particularly subject to whirlwinds, advancing in the figure of an immense column, with irregular motion, great noise, and considerable rapidity. Clouds of dust are carried up by the column, which is 20 or 30 feet in diameter at the base, to a greater height than the eye can reach. Sometimes tents are beat down in its progress; and the only dress of their inmates swept half a mile away, while a close pursuit is necessary to recover it. Satarah, a strong hill fort and tower, stands at the summit of a declivity ascending several miles, distant 16 leagues from Poonah. Its name, according to some, signifies a star, being the form in which it is built; or, according to others, 17 walls, 17 towers, and 17 gates, with which it is said to be provided. It is accessible only by a very narrow path, admitting a single person at a time. In the year 1651, it was taken from the sovereign of Bejapour by the founder of the Mahratta empire; and here the descendant of the captor is still imprisoned. It should be understood that the Peshwa who is invested with the real authority, is only the representative of the head of the Mahrattas, while the sovereign enjoys nothing but nominal power, and is kept in a situation of restraint. But the Peshwa must nevertheless be invested in office by him, and he receives some external demonstrations of authority, though deprived of liberty, and is otherwise slenderly provided for.

History of this Province.

Bejapour is therefore a populous and flourishing province, and one which, with its capital, has held a distinguished place in history. Four-fifths of it pertain to the Mahrattas; the remainder to the Nizam. It formerly constituted an independent sovereignty, with the antiquity of which we are not acquainted, farther than that Abou al Muzuffir Eusuff Adil Shah was the founder of the Adil Shawee, one of the principal dynasties. The father of this prince, dying in the year 1450, his brother, to obviate all disputes about succession to the kingdom, directed that he should be put to death; but the Sultana his mother, having prevailed on the executioners appointed by this barbarous order to spare her innocent child a single day, studied to devise the means of his preservation. She sent immediately for Khajeh Ummed ud Dien, a merchant accustomed to supply her household, inquiring how many slaves he had for sale; and finding he had five Georgian and two Circassian boys, selected one of the latter who bore the greatest resemblance to her own son. He was strangled, and brought out in a shroud, without any suspicion being excited of the deception. The Sultana then induced the merchant to hasten with the young prince to a secure retreat, out of the Mahometan dominions; and he repaired with his charge to a town in Persia. There the prince attained many accomplishments, and remained until reaching the age of eighteen, when he resolved to revisit Hindostan, He soon obtained an important appointment in one of the courts of that country; and, by a series of good fortune, ascended the throne of Bejapour in the year 1489. His reign was long and prosperous; he patronised learning; encouraged the residence of foreign artists; the kingdom flourished; and his death was deeply regretted as a misfortune by his subjects. The fourth in succession from this prince was Ibrahim Adil Shah, who, attacked by a complication of disorders, put to death the physicians unable to effect his cure; decapitating some, and trampling others under the feet of elephants, which excited such an alarm, that all the survivors fled beyond his boundaries. In the year 1665, the governor of the Deccan was directed to render himself master of Bejapour. The natives were defeated, though they had an army of 80,000 horse, their general was killed, and the survivors pursued within ten miles of the capital. Aurungzebe renewed his invasion in 1668, and besieged the city in person; but the inhabitants defended themselves with great resolution. The country had been laid waste, supplies were intercepted, and so great a body of people confined in a restricted space began to be distressed for provisions. Meantime, the hostile batteries having effected sufficient breaches, preparations were made for an assault; but the inhabitants, apprehensive of the issue, resolved to capitulate, and the king surrendered himself to the Mogul emperor, by whom he was treated honourably; for one of his sisters had been married to a son of Aurungzebe; and his principal officers received marks of distinction. Aurungzebe entered the fort through the breach by which the assault was to have been made, and, repairing to the great mosque, already damaged by his cannon, offered up a thanksgiving for his success. But the internal tranquillity of Bejapour had been previously weakened by the revolt of Sevajee, the founder of the empire of the Mahrattas. They did not view the invasion of the Mogul emperor without jealousy; and, as their own power was constantly augmenting after his decease in 1707, they gradually compelled his successors to withdraw. Descending to a later period, we find that they had been unable to reduce the country to order and quietness; and, after a keen contest between them and the British, which terminated in the year 1804, their whole territory was in a state of anarchy. The authority of the Peshwa was either resisted or denied, and scarcely extend-

Bejapour || Bell Rock.

ed beyond his capital, Poonah. The country was occupied by lawless depredators, and all the subordinate chiefs were rebellious and dissatisfied. It was found expedient for the British government to interpose, and endeavour to restore tranquillity,—a laudable measure, which was in a principal degree effected by the prudence and moderation of Sir Arthur Wellesley, now Duke of Wellington. He preserved many of the chiefs from the vengeance which their leader had resolved to take upon them, and induced them to recognise his authority, in paying the service due. Nevertheless, it is easy to anticipate, that, if their union is preserved, they will steadily resist the approaches of foreign nations towards their territory, and most probably will prove a material obstacle to the further aggrandizement of the British in Hindostan. (s.)

BELL ROCK LIGHT-HOUSE. The accompanying Plate (XXXIII.) exhibits a perspective view of this important national edifice (which has not improperly been termed the *Scottish Pharos*), as it is seen after a gale at north-east. In describing it we shall first notice the position of the rock, and circumstances connected with it, and then describe the progressive advancement and finishing of the building.

Description of the Bell Rock.

The *Inch Cape*, or Bell Rock, is situate on the north-eastern coast of Great Britain, about 12 miles in a south-western direction from the town of Arbroath, in the county of Forfar, and about 30 miles in a north-eastern direction from St Abb's Head, in the county of Berwick; and, as may be seen from the charts of that coast, it lies in the direct track of the Firth of Tay, and of a great proportion of the shipping of the Firth of Forth which embraces the extensive local trade of the populous counties of Fife, Clackmannan, Stirling, Linlithgow, Edinburgh, and Haddington; and which being an admiral's station, is now the rendezvous of the North Sea fleet. This estuary is, besides, the principal inlet upon the eastern coast of Britain, in which the shipping of the German Ocean and North Sea take refuge, when overtaken by easterly storms. When the tides are neap, or at the quadratures of the moon, the Bell Rock is scarcely uncovered at low water; but, in spring tides, when the ebbs are greatest, that part of the rock which is exposed to view at low water measures about 427 feet in length, by 230 feet in breadth; and, in this low state of the tides, its average perpendicular height above the surface of the sea may be stated at about four feet. Beyond the space included in these measurements, at very low tides, there is a reef on which the larger kinds of fuci appear floating at the surface of the water. This reef extends about 1000 feet, in a south-western direction from the higher part of the rock just described, on which the light-house is erected. The whole rock is composed of sandstone of a red colour, with some spots of a whitish colour. It strongly resembles the rocks forming the promontory on the Forfarshire coast, called the Red Head, and those also of the opposite shores of Haddington and Berwick shires, near Dunglass. The stone is hard, of a fine grain, and contains minute specks of mica. Its surface is rugged, with holes which, at ebb-tide, form small pools of water. Such parts of the rock as appear only in the lowest tides, are thickly coated with fuci; the larger specimens are Fucus digitatus, *great tangle*, and Fucus esculentus, or *badderlock*, a sea-weed which sometimes attains here the length of 18 or 20 feet. Those parts most frequently left by the tide are covered with small shell-fish, such as the common barnacle, the limpet, the whelk, and a few common muscles; and some very large seals rest upon its extremities at low water of spring-tides. At high water, the red ware cod is caught over the rock; and at a distance from it, as the water deepens, the common cod, haddock, whiting, skate, holibut, and other fishes common in these seas, are very numerous.

Dangerous position of the Rock.

Such being the position and nature of the Bell Rock, lying in the direct track of a numerous class of shipping, and appearing only a few feet in height above the water, and that only at the ebbs of spring-tides, being at high-water wholly covered to the depth of from 10 to 12 feet; the want of some distinguishing mark that might point out its place was long felt by the mariner, and of the utility and necessity of this, every returning winter gave the public fresh proofs. But it required a great extent of commerce to afford the probability of raising an adequate revenue, by a small duty or tonnage upon vessels passing it, to meet the risk and expence of such a work, as the erection of a habitable house about 12 miles distant from the nearest land, and on a rock from 10 to 12 feet wholly under water at spring-tides. We have read of the wonderful extent of the Pharos of Alexandria, and are acquainted with the Tower of Corduan, erected upon a small island at the entrance of the Garonne, on the coast of France, and know, more particularly, the history and structure of the Eddystone light-house, built upon a small rock lying 12 miles off the coast of Cornwall. The public is in possession of Mr Smeaton's perspicuous and valuable account of that work; but it is to be observed, that, in the erection of a light-house upon the Bell Rock, independently of its distance from the main-land, a serious difficulty must here have presented itself, arising from the greater depth of water at which it was necessary to carry on the operations, than in the case of any former building of this kind.

Tradition tells us, that so far back as the fourteenth century, the monks of Aberbrothick caused a large bell to be suspended, by some means or other, upon the Rock, to which the waves of the sea gave motion, the tolling of the bell warning the mariner of his approaching danger. From this circumstance it is said the Rock got its present name, but in so far as can now be discovered, there is no record of this contrivance; and it seems more probable that, at an early period before the wasting effects of the sea had brought the Rock into a state so low and mutilated, some part of it may have resembled a bell in appearance, and have thus given rise to the name.

Preparatory Measures.

Although the dangers and the inconveniences of this Rock, and of the coast in general, were long and severely felt by the shipping of the eastern coast of Great Britain; yet, till of late, there was no constituted body for the erection of light-houses in

Bell Rock.

Scotland; such an appointment necessarily supposes a more extensive trade than that part of the united kingdom possessed prior to the union of England and Scotland; and even long after that happy event, the finances of the country were not in a state to warrant expensive undertakings of this nature. About the middle of the last century, however, when the improvement of the highlands and islands of Scotland was viewed as an object of great national importance, the establishment of light-houses upon that coast was found indispensably necessary to the extension and success of the British Fisheries. This subject was accordingly agitated in the Convention of the Royal Burghs of Scotland; and, in the year 1786, a bill was brought into Parliament, appointing the Lord Advocate and Solicitor-General of Scotland, the Sheriffs-depute of the maritime counties, and the chief Magistrates of certain of the Royal Burghs, *ex officio*, to act under the title of the *Commissioners of the Northern Light-houses*; and a certain duty on tonnage upon shipping was granted to them, for the erection and maintenance of such light-houses as they should find necessary to erect upon the coast of Scotland. But when a sufficient number of Light-houses are erected upon the coast, and a fund accumulated for their maintenance, the act provides, that the light-house duties shall cease and determine. These Commissioners, in virtue of the powers vested in them, proceeded to the immediate improvement of such accessible points of the coast as suited the infant state of their funds; and, in the course of a few years, eight of the principal headlands between the Firths of Forth and Clyde, including the Orkney Islands, were provided with light-houses, erected upon the most approved principles of the time, by the late Mr Smith, engineer for the Light-house Board. Keeping always in view as a principal object the erection of a light-house on the Bell Rock, the Commissioners, independently of these highly useful and important works, were gradually accumulating a fund for this purpose, in order to undertake that work as soon as their limited means would admit. In the month of December 1799, the occurrence of a dreadful storm rather tended to hasten this measure. The wind for two days was excessive, and being from the south-eastern direction, all the ships were driven from their moorings in the Downs and Yarmouth Roads. No fewer than about 70 vessels were wrecked, and with many of their crews were totally lost, upon the eastern coast of Scotland; a calamity that more especially directed the attention of the country and of the Commissioners, to the erection of a light-house upon this Rock; as, in this particular instance, a light-house there would have opened the Firth of Forth, as a place of safety to many, which, to avoid the hidden dangers of the Rock, were lost in attempting to get to the northward of the Firth in this storm.

After the loss of so many lives, and much valuable property, various measures were taken for the erection of a light-house upon this Rock. In the year 1803, a bill was brought into Parliament, which, with some alterations, ultimately passed both Houses, in the session of 1806; by which the northern light duty of three halfpence *per* ton on British vessels, and threepence *per* ton on foreign bottoms, was extended to all vessels sailing to or from any port between Peterhead to the north, and Berwick-upon-Tweed to the southward. This bill also empowered the commissioners to borrow L. 25,000 from the *three per cent. consols*, and having already accumulated the sum of L. 20,000 of surplus duties, with this *loan* from Government they were enabled to commence the operations at the Bell Rock with a disposable fund of L. 45,000.

Several plans for the erection of this light-house had for a considerable time been in contemplation, and were submitted for consideration of the Light-House Commissioners. Captain Brodie of the Navy constructed a very ingenious model of a cast-iron light-house to stand upon pillars; and Mr Murdoch Downie, author of several marine surveys, brought forward a plan of a light-house, to stand upon *pillars of stone*. Mr Telford, the engineer, was likewise employed in some preliminary steps, connected with Mr Downie's inquiries. In the year 1800, Mr Stevenson, engineer for the Commissioners of the Northern Light-houses, modelled a design applicable to this situation; and having, by their directions, made a survey and report relative to the situation of the Bell Rock, which was published by the Board, along with a letter from Admiral Sir Alexander Cochrane, when he commanded his Majesty's ship Hynd, upon the Leith station, in 1793, recommending the erection of a light-house on this Rock; these, with other documents, were afterwards submitted to Parliament, in a memorial from the Commissioners, drawn up by Robert Hamilton, Esq. advocate, one of their number; when application was made for a loan from Government. So different, however, were the views taken of the subject, and so various and doubtful were the opinions of the public about the kind and description of building best suited to the peculiar situation of the Rock, and even with regard to the practicability of a work so much under the surface of the water, and where so large a sum of money was necessarily to be expended, that the Commissioners thought it advisable to submit the matter to the opinion and advice of Mr Rennie. This eminent engineer coincided with Mr Stevenson in preferring a building of stone upon the principles of the Eddystone light-house, which being approved of and adopted, the execution of the work was finally committed to these gentlemen.

Bell Rock Floating-Light.

The bill having passed late in the session of 1806, in the following summer a vessel was fitted out as a floating-light, for which the act of Parliament made provision, and she was accordingly moored off the Bell Rock in the month of July 1807. During the first season of the operations, this vessel was used as a *Tender*, to which the artificers retired while the Rock was covered with water. Her station was about a mile and a half north-east from the Bell Rock, and her moorings consisted of a *mushroom anchor*, weighing 33 cwt. and a weighty chain laid down in 22 fathoms water, and at these moorings she rode by

Bell Rock.

a strong hempen cable, measuring 14 inches in circumference, without accident, during the four years in which the light-house was building. This vessel was rigged with three masts, each of which carried a lantern, which, in a curious manner, was made to embrace the masts; and, by this means, the use of cumbrous yards and spars over head were avoided; and as each mast passed through the centre of its respective lantern, on which it traversed, the light was not obscured on any side. Each of these lanterns contained ten lamps, with as many small silver-plated reflectors; and thus, by the appearance of three distinct lights (the centre one being the highest), the Bell Rock floating-light formed a triangular light, and was easily distinguishable from the *double and single lights* upon the coast, and rendered immediate and essential service to the trade and shipping of the coast.

Operations of 1807.

Early in the spring of 1807, stones were collected from the granite quarries of Rubeslaw in Aberdeenshire, for the *outside casing* of the first 30 feet, or lower part of the building; those of sandstone for the hearting, or interior of the solid, and also for the higher parts of the building, were got from Mylnefield quarry, near Dundee. For the conveniency of the work, the cornice and parapet-wall of the light-room were hewn and prepared at Edinburgh, and the stones for these parts were accordingly taken from the quarry of Craigleith. At Arbroath, the most contiguous harbour to the Bell Rock, a piece of ground for a work-yard was procured on a lease of seven years, the supposed period for the duration of the works; and here the works were conducted; materials were laid down, and workmen collected; shades were also constructed, and a barrack erected for the accommodation of about 100 artificers when they landed from the Rock, that they might be at a call, by night or day, when required to sail for the works at the Rock. These previous steps being taken ashore, the operations at the Rock itself commenced in the month of August 1807.

Wooden Beacon-House.

The first attention at the Bell Rock was to erect a place of refuge for the artificers, in the event of an accident befalling any of the *attending-boats*,—a circumstance which, if unprovided for, might not only involve the safety of every person employed at the *out-works*, but prove a serious check to the future progress of the undertaking, which could only be proceeded in at low water of spring-tides, when two and a half or three hours were considered a good tide's work. From this circumstance, it became necessary to embrace every opportunity of favourable weather, as well in the day tides as under night by torch-light, and upon Sundays. In the early stages of the business, the flood-tide no sooner began to cover the exterior parts of the Rock, than the workmen were obliged to collect their tools and apparatus, and betake themselves to the attending-boats, before the water burst in upon them. These boats were rowed often with the utmost fatigue and difficulty to the floating-light, where the workmen remained till the Rock began to make its appearance again at next ebb-tide. Happily no accident occurred during this perilous part of the work, to check the ardour of the artificers, nor to retard their progress, and by the latter end of October, the beacon, consisting of twelve large beams of fir-timber, was erected, having a common base of 30 feet, and rising to the height of 50 feet above the surface of the Rock. These spars were of fir-timber, strongly framed with oak-knees, conneeted to the Rock with iron-bats of a particular construction, set into holes, cut about 18 inches in depth, and wedged into their places, first with slips of fir, then with slips of oak, and, lastly, with pieces of iron. The upper part of this beacon was afterwards fitted up, and occupied as a place of residence during the working months. The lower floor was employed as a smith's forge, and also for preparing mortar for the building. The cook-house was immediately over this; the next floor was occupied by the cabins of the engineer and foremen, and over all was the barracks for the artificers, whose hammocks were ranged in tiers of five in height. The dwelling or lodging part of this temporary residence was above the reach of the sea in moderate weather, but the lower floor was often lifted by the waves, when the lime casks, and even the *smith's anvil* and apparatus, were frequently washed away. The *beacon-house*, so constructed, was erected near the site of the light-house, and in the more advanced state of the work, was connected with it by a wooden bridge; which was also of the greatest utility as a stage in raising the materials from the Rock to the building. A little reflection upon the singular position and circumstances of the Bell Rock, will show the great and indispensable use of this beacon-house in facilitating the operations. Unless some expedient of this kind had been resorted to at a work so much under water, the possibility of erecting a light-house here is extremely doubtful: at any rate, it must have required a much longer period for its accomplishment, and, in all probability, many lives would have been lost in the progress of the operations.

Second Season's Operations of 1808.

The circumstance of the beams of the beacon having withstood the storms of winter, inspired new confidence in the artificers, who now landed upon the Rock in the summer of 1808 with freedom, and remained upon it without fear till the tide flowed over it. Although it required a considerable part of the summer to fit up the beacon as a barrack, yet it was in a state sufficient to preserve the workmen in case of accident to the boats. The great personal risk and excessive fatigue of rowing boats, crowded with the artificers, every tide to the floating light-vessel was now also avoided by an additional vessel having this season been provided, and entirely set apart for the purpose of attending the Rock. This vessel was a very fine schooner of 80 tons. Her moorings were so constructed, that she could be cast loose at pleasure, and brought to the lee-side of the Rock, where she might at once take up the artificers and their boats in bad weather, instead of their having, as formerly, to row often against both wind and tide, to the more distant position of the floating light. From this circumstance, it was now found practicable both to commence the works at the Rock much earlier, and to continue them to a later period. Being now provided with a place of safety, by the erection of the spars of the beacon-house, and having a

Bell Rock.

tender always at command, which could be cast loose, in case of need, the works now went forward even in pretty rough weather; and thus struggling both during the night and day tides, the site of the light-house was prepared, and cut to a sufficient depth into the Rock; and on the 10th of July 1808, the foundation stone of the building was laid. In the course of this season, tracks of cast-iron railways were also fixed upon the Rock, from the different landing places to the building, calculated for conveying blocks of stone of two or three tons weight along the Rock; and by the latter end of the season's operations the first four courses of the Light-house were built, which brought it to the height of five feet six inches above the foundation.

Third Season's Operations, 1809.

In the course of the winter preceding the third season's operations, the works at the Rock were frequently visited, and, in the spring of the year 1809, were resumed with new vigour; and it was no small happiness to find, that not only the four courses of the light-house built last season were in perfect order, after a long and severe winter, without the least shift or change of position, but that even the beacon-house and railways were little injured, being almost in a state of readiness for resuming the operations. The first thing to be done was to lay down sets of chain moorings, with floating buoys for the tender, and for the flush-decked praam-boat, stone lighters, and vessels employed at the Rock, and to erect the necessary apparatus and machinery for landing the stones, and laying them in their places upon the building. These arrangements being made, every thing went forward in the most prosperous manner; and, by the month of September, the building was got to the height of 30 feet, which completed the solid part of the light-house. After obtaining this height, from the advanced state of the season, Mr Stevenson did not find it advisable to risk the machinery and apparatus longer, and the building was left in this state for the winter months.

Fourth Season's Operations, 1810.

At the commencement of the fourth and last season's work, it was a matter of some importance for the preparation of the higher or finishing parts of the building, to ascertain whether it would be possible to carry the masonry from the height of 30 feet to 100 feet in the course of this summer; but it was extremely doubtful whether this could be accomplished, so as to secure good weather for fitting up the light-room, and completing the more delicate operations of the painter and glazier, connected with it. Under these uncertain prospects, the work was begun in 1810, at as early a period as the weather would at all admit. From the great number of finished courses of prepared stone at the work-yard, which had been tried upon the platform, numbered and ready to be shipped from Arbroath for the Rock, there was only the winds and tides to contend with; and even these were, in effect, wonderfully softened and allayed, by the enterprising exertions and thorough practice of the seamen and artificers, during four successive seasons; which had given much dexterity to the several departments, both in the work-yard at Arbroath, and at the Rock, where the operations of the builder and of the landing-master's crew were conducted with much skill and activity.

Bell Rock.

Taking these mainly into account, and by a fortunate train of circumstances, the masonry of the building was completed in October; and the light-room being finished in the month of December, the light was advertised to the public, and exhibited for the first time from the new Light-house on the evening of the 1st of February 1811; and, on the same night, the floating light-vessel was unmoored, and that temporary light discontinued.

Description of the Light-house.
